The two strands of scientific ontology, as I have described them, overlap in many contributions but there is a major difference between them. A premise of the first strand of scientific ontology is that the practices of scientists in their target field or discipline are worthy of detailed scrutiny, though in some cases this scrutiny may be justified by institutional and sociological factors rather than epistemological ones. There is therefore a tendency in some parts of the literature to take the fact of knowledge production within the social sciences at face value. In the second strand, reference to the social scientific literature acts as the entry point into a more sustained analysis of social scientific concepts, which attempts to go beyond current disciplinary strictures and reorient social theory. Contributors to the literature on philosophical ontology have even more comprehensive and radical ambitions.

Philosophical Ontology

The project of philosophical ontology may be contingently related to scientific ontology by the fact that leading scholars usually engage with the work of others prior to the development of their own framework, but authors engaged in what I have called philosophical ontology are ultimately best thought of as system-builders. In other words, the intention of contributors to this literature is to develop and articulate conceptions of social being that constitute better, or more complete accounts of the social world than incumbent or competing views. This is a more ambitious project than the research that I have described under the heading of scientific ontology in Section Scientific Ontology and it is generally regarded as being more controversial. Moreover, proponents of philosophical ontology have readily engaged in critical debates within the social scientific disciplines, using their ontological perspective to inform and shape their critiques of extant theoretical contributions. Thus philosophical ontology is a critical, revisionary, and interactive project within the social sciences.

The contributions of Roy Bhaskar and John Searle stand out for their level of detailed elaboration and subsequent influence within the social sciences. Both perspectives are informed by philosophy, but one (Bhaskar's) emanates directly from the problems of the social sciences, whereas the other (Searle's) is principally motivated by problems in the philosophy of mind and language. I shall now discuss each briefly in turn before briefly describing a potentially significant difference between them in Section Naturalism and Emergence.

Starting from insights that were consistent with developments in contemporary philosophy of science, Bhaskar (1975) argued for a realist conception of science and developed the position known as critical realism in the social sciences (check cross-reference for CR). His general conception is notable for its reliance on a transcendental argument to move from the observation of regularities in events (surface phenomena) to positing the existence of the deeper, unobservable mechanisms that cause them. According to Bhaskar, in the

domain of the natural sciences, the mechanisms under investigation are relatively enduring and do not depend on the activities of humans for their continuing existence.

Bhaskar extended his argument to social mechanisms that depend on human activities in his seminal book *The Possibility of Naturalism* (Bhaskar, 1979). Whilst in the case of the natural sciences Bhaskar starts with experimental activity and moves, through a process of abduction, to their conditions of possibility, he takes a different tack in the case of the social sciences. Rather than beginning with the practices of social scientists – whose results and methods are deemed to be less credible than their peers in physics or biology – Bhaskar begins with everyday social practices themselves. From these, he infers that social ontology is necessarily 'relational' in the sense that all social entities are defined by and exist by virtue of their relations to other entities. This relational ontology coupled with the existence of intentionality (understood as the 'directedness' or 'aboutness' of human mental states), which differentiates the social from the natural realm, allows Bhaskar to develop the transformational model of social activity (TMSA).

The TMSA is the most influential articulation of a philosophical ontology currently available to social scientists. Amongst others, it has been used by leading scholars in sociology (Margaret Archer, Andrew Sayer), law (Alan Norrie), economics (Tony Lawson), organization studies (Mike Reed), political economy (Bob Jessop), and international relations (Colin Wight). The TMSA conceives of the social world as an open system populated by active intentional actors. Individuals are not isolated atoms, but evolve within an institutional environment characterized by emergent social structures that are inherited from prior generations. The temporal and processual nature of social life is recognized in this social ontology as each new generation of actors adopts, rejects, or transforms inherited structures from its predecessors.

John Searle's influential contribution to the philosophy of the social sciences 'The Construction of Social Reality,' constitutes an attempt to build a realist account of social ontology from a mixture of commonsense and natural scientific insights (Searle, 1995). Like Bhaskar, he does not regard the efforts of social scientists as a legitimate basis for the articulation of his ontological perspective. Instead, Searle takes the findings of the natural sciences and in particular commitment to both physicalism and the findings of evolutionary biology as the starting point of his analysis. Yet he nevertheless sees a distinct place for the elaboration of a social ontology based on three characteristics of human collectivities that distinguish them from the physical systems analyzed by the natural sciences. His approach is founded upon these three key characteristics, which are the building blocks of his social ontology. When combined, collective intentionality, the assignment of function and constitutive rules allow him to build a comprehensive picture of the social domain.

The first building block, collective intentionality, refers to the human ability to share intentional states with others, such that one can legitimately say 'we believe,' 'we desire,' or 'we intend' (check cross-reference for CI). In invoking the second building block of his philosophical ontology, Searle emphasizes the ability to collectively assign functions to objects by adopting shared attitudes toward them. He claims that even the 'natural' function of the heart (to pump blood) is collectively attributed against a background teleology that values life and survival (Searle, 2006). His third building block is the notion of a constitutive rule. The existence of constitutive rules allows the attribution of a status to an object that is not dependent on or connected to its physical structure. Money can be a coin, a piece of paper, a plastic card or an electronic signal, so long as we collectively agree to treat it as money. Searle sums up his position in the following terms: "I have tried to state the logical form of the assignment of a status function when it becomes regular, and thus a matter of a rule, as that of the constitutive rule of the form, X counts as Y, or more commonly, *X counts as Y in context C*. Thus, such and such counts as a $20 bill in our society" (2006: p. 18).

Naturalism and Emergence

I end this article on a note of divergence between the two influential approaches to philosophical ontology that I have just outlined. A natural question for any critically minded reader of the literature on social ontology is to ask oneself: 'Why do we need a specifically 'social' ontology?' What is so different about social being that it requires a different conceptual toolkit to the one provided by the natural sciences?

One response might be to invoke the existence of a social substance that is somehow separate from and different to the substance studied by the natural sciences. But this response is rejected by the vast majority of secular philosophers and social scientists, including most social ontologists. There is a widespread desire to adhere to some form of ontological naturalism; in other words, to accept that whatever substance or material undergirds our experience of the natural and social worlds is common to both. Searle explicitly states his desire to present a systematic ontology of the social world that is consistent with the findings of physics and biology. Yet both Searle's and Bhaskar's approaches require some account of the emergent properties of organized (social or biological) systems, which may be difficult to reconcile with physicalism (check cross-reference on emergence).

Searle's framework is ultimately reducible to the mental properties of individual agents, even though these contain irreducible social concepts such as 'we-intentions.' His ontological individualism (check cross-reference on Meth Individualism) rests on a complex neurophysiological substratum to which individual mental states cannot be reduced. For Searle, therefore, it is the emergence of human consciousness in the form of mental states which can be shared and employed collectively that necessitates the development of a specifically social ontology. For Bhaskar, however, social relations, rules, and institutions are seen as emergent properties of human collective activity that cannot be reduced to the mental states of participants. This difference has further implications for where the mechanisms investigated by social scientists are located. A Searlian social ontology does not recognize the causal powers of supra-individual entities, whereas the TMSA does.

Social Phobia across the Lifespan

Abstract

Social anxiety disorder is characterized by fear and avoidance of social situations in which one may be evaluated by others. The disorder results from a complex interplay among genetic factors (e.g., family history of the disorder); temperamental factors (e.g., behavioral inhibition and anxiety sensitivity); biological contributors; parenting style and other environmental considerations; and cognitive factors, such as *interpretation biases* and heightened self-focused attention. In this article, we discuss the contribution of these factors for the etiology and maintenance of the disorder throughout the lifespan.

Introduction

Social anxiety disorder (SAD), also referred to as Social Phobia, is a chronic and debilitating disorder (Kessler et al., 2005) that differs in prevalence and manifestation among different cultures (Heinrichs et al., 2006; Hofmann et al., 2010). According to the current Diagnostic and Statistical Manual of Mental Disorders (DSM-V; American Psychiatric Association, 2013), SAD is characterized by persistent fear of negative evaluation, typically presenting as severe distress in and/or avoidance of situations where the individual could be scrutinized by others. These include initiating or maintaining conversations, attending social events, dating, interacting with authority figures, eating or writing in public, and particularly public speaking, the most common fear in individuals with SAD (Pollard and Henderson, 1988). Such symptoms cause distress and often lead to impairments in social relationships, as well as educational and professional development (American Psychiatric Association, 2013; Stein and Kean, 2000).

In the previous edition of the DSM (i.e., DSM-IV-TR; American Psychiatric Association, 2000), clinicians were instructed to consider the generalized subtype if the individual feared or avoided most or all social situations. Otherwise, the person met criteria for the less pervasive nongeneralized subtype of SAD. There was debate as to whether these subtypes of SAD represented qualitatively different syndromes, distinct subgroups within a syndrome, or a continuum of severity within one group (Hofmann et al., 2004a,b; McNeil, 2001). The distinction is further complicated by high comorbidity between the generalized subtype and Avoidant Personality Disorder (APD; Schneier et al., 1991), which has several overlapping symptoms with SAD. This has prompted the suggestion that APD and subtypes of SAD may lie along a spectrum of severity (Hofmann et al., 2004a,b; McNeil, 2001). However, there is evidence that differentiates APD, the generalized subtype of SAD, and nongeneralized subtypes. These include different ages of onset (Mannuzza et al., 1995), physiological versus subjective anxiety profiles in response to behavioral challenge (Heimberg et al., 1990; Hofmann et al., 1995b; Boone et al., 1999), as well as cognitive processing (Hofmann, 2007). Nevertheless, the most recent edition of the DSM (i.e., DSM-V; American Psychiatric Association, 2013) no longer recognizes the generalized subtype. Instead, it has a 'performance only' specifier to capture cases in which an individual only has symptoms during public speaking/performance situations. However, it remains to be seen whether this change is empirically justified and clinically useful. A recent study examined the rates and correlates of this new DSM-V specifier in a sample of 204 treatment-seeking children and adolescents with SAD (Kerns et al., 2013). When applying the DSM-IV subtype classification, 64.2% of the sample was classified as having a generalized subtype of SAD, with the remaining 35.2% classifying as having a nongeneralized subtype SAD. Participants with generalized SAD were older, had more clinically severe SAD, showed greater depressive symptoms, and were more likely to have a comorbid depressive disorder than those with nongeneralized SAD. In contrast, no children in this sample endorsed discrete fear in performance situations with an absence of fear in other social situations, questioning the meaningfulness of the new DSM-V specifiers in treatment-seeking youth with SAD.

SAD can occur at all stages in life and is shaped by developmental factors (Ollendick and Hirshfeld-Becker, 2002). Consistent with the transactional model (Sameroff, 2009), which posits change as continuous reciprocal interactions between the individual and his or her environment, SAD develops over time as a product of genetic, temperamental, physiological, cognitive, and various environmental factors. Shaped by interactions among these factors, the individual is both an active agent and a recipient of external influences. In a pathological context, the integration of factors contributing to development can fail and lead to poor adaptation, which, in the case of SAD, is the failure to comfortably navigate social situations. Within this framework, we will summarize the developmental course of SAD and the developmental factors in its etiology and maintenance, including genetic, temperamental, physiological, parental, environmental, and cognitive factors.

Developmental Course of SAD

Prevalence throughout the Lifespan

Recent estimates suggest that between 5 and 12% of people will meet DSM-IV diagnostic criteria for SAD at some point in their lives (Grant et al., 2005; Merikangas et al., 2010; Kessler et al., 2005). Most adults with generalized SAD report having experienced social anxiety for as long as they can remember (Bourdon et al., 1988).

Because individuals with social anxiety often fear being negatively evaluated by others, it is reasonable to imagine that the prevalence of SAD in childhood and adolescence might increase with age, as individuals become increasingly aware of others' capacity to judge them. Indeed, the prevalence of SAD in preadolescent children has consistently been found to be very low, usually well below 1% (Cartwright et al., 2006). This is consistent with research documenting the mean age of onset for symptoms of SAD at 13–15 years old (Kessler et al., 2005; Grant et al., 2005). Both healthy and anxious individuals experience increased anxiety related to social situations over the course of childhood and adolescence (Ollendick et al., 1989; in Ollendick and Hirshfeld-Becker, 2002), including modest increases from mid to late adolescence (Merikangas et al., 2010). It is rather uncommon for SAD to develop after young adulthood (Beesdo et al., 2009) or during old age, with typical estimates around 2–4% (e.g., Karlsson et al., 2009). Taken together, it seems clear that SAD is not displayed equivalently throughout the lifespan.

Age-Dependent Presentation

Given the important role of situational factors in SAD, it is unsurprising that SAD often manifests itself differently across age groups. The same fear of negative evaluation may prompt anxious children to miss school, young adults to avoid dating, and older adults to decline friends' invitations to keep in touch. More specifically, behaviors that characterize SAD in young childhood (e.g., crying, refusing to leave a caregiver) may be replaced by other behaviors in older individuals (e.g., avoidance of social situations, which is impossible for very young children; Ollendick and Hirshfeld-Becker, 2002). Furthermore, the subjective experience of social anxiety is different in young children compared with older children and adults. Young children are more likely to feel overwhelmed by an intense rush of distracting thoughts in social situations, while older children and adults report a greater frequency of specific negative beliefs about the self and fears of negative evaluation. Older individuals are more likely to see that their fears are excessive (Ollendick and Hirshfeld-Becker, 2002), although this recognition does not necessarily relieve suffering.

Just as SAD may present itself differently at different ages, functional impairment also varies with age, although high levels of life interference are common across most sufferers. In school-age children, missing school and poor academic performance (e.g., skipping presentations or failing to participate in class) are of significant concern. In young and middle adulthood, difficulties may shift toward finding and keeping a job and getting married (Hofmann and DiBartolo, 2010). SAD decreases work productivity (Wittchen et al., 2000), earning potential (Schneier et al, 1992) and career-promoting behavior (Phillips and Bruch, 1988). While older adults may be less concerned with finding a mate or keeping a job, functional impairment is no less serious in later life given the negative health effects associated with a weak social support network.

Treatment Considerations

When left untreated, SAD is unlikely to remit spontaneously. In fact, research consistently demonstrates that without treatment, it follows a chronic and often pervasive course (Davidson et al., 1993; Liebowitz et al., 1985; Schneier et al., 1992, 1994; Stein and Kean, 2000; Stein et al., 1996, 2000). Fortunately, a number of effective treatments exist, most notably cognitive behavioral therapy (e.g., Hofmann and Otto, 2008). Such treatments have to take into account the unique advantages and limitations of the individual's life stage. For example, opportunities for social interaction tend to decline with age, making treatment of SAD a challenge in older adults. A danger of misdiagnosis exists for young children with SAD. Comorbidity is high between SAD and selective mutism as well as depression (Ollendick and Hirshfeld-Becker, 2002). Some socially anxious children behave in ways that lead to erroneous diagnoses, as when avoidant children are misclassified as displaying oppositional defiance (Ollendick and Hirshfeld-Becker, 2002).

Genetic Factors

There is clear evidence for the notion that SAD is familial (Stein et al., 1998). Stein et al. (1998) found that individuals with a first-degree relative with SAD are 10 times more likely to have SAD than those without socially anxious relatives. There is consensus that this family liability is, at least in part, due to heritable genes (Hettema et al., 2001; Stein and Gelernter, 2010).

In an attempt to identify which specific genes are associated with SAD, several molecular genetic studies have been conducted (see Norrholm and Ressler, 2009; Domschke and Dannlowski, 2010). These studies have been scarce, mainly focusing on the SERT gene (SLC6A4), which codes for serotonin transporter protein (Stein and Gelernter, 2010). For example, Furmark et al. (2004) found that 5HTTLPR, a polymorphism of the SERT genetic locus often associated with psychiatric disorders, was associated with symptom severity in individuals with SAD, as well as enhanced activity in their amygdala when anxiety was induced. Another study has also found some evidence for the association of circadian genes (e.g., ARNTL2 and DRD2) with SAD (Sipilä et al., 2010). However, it must be cautioned that the existing studies do not provide definitive proof linking these genes to SAD, given lack of replication, low power, and the continuing debate regarding the delineation and validity of the phenotype.

Investigators have attempted to overcome these difficulties, which are relevant for any psychiatric genetics research, by studying endophenotypes (i.e., intermediate phenotypes) of SAD. That is, instead of studying samples with SAD, these studies focus on meaningful and presumably more homogenous subsamples of individuals with particular traits important in SAD. For example, it has been found that 5HTTLPR is associated with shyness (Arbelle et al., 2003; Furmark et al., 2004), and that the association between 5HTTLPR and introversion, another trait linked to SAD, is moderated by variants of a gene that codes for brain-derived neurotropic factor (BDNF), demonstrating a gene by gene interaction (Terracciano et al., 2008, 2010). Low extraversion has also been associated with the gene-encoding regulator of G protein signaling 2 (RGS2; Smoller et al., 2008) and the dopamine D4 receptor gene (DRD4). The related trait of neuroticism has been associated with MAMDC1 (van den Oord et al., 2008) and SNAP25 (Terracciano et al., 2008). The trait with the strongest genetic liability in relation to SAD is behavioral inhibition, as shown in various studies (e.g., Stein and Gelernter, 2010). This temperament has been associated with the glutamic acid decarboxylase gene that encodes a GABA synthesis enzyme (Smoller et al., 2001), as well as the CRH and RGS2 loci (Smoller et al., 2003, 2008). We will discuss this trait in more detail in the following paragraphs.

Temperamental Factors

Behavioral Inhibition

Behavioral inhibition (BI) is a childhood temperament, first described by Kagan et al. (1984) that occurs in approximately 10–15% of white American children. It is associated with fear, avoidance, restraint and long latencies to approach in the face of unfamiliar persons, objects, or situations. Although not all children high in BI will develop SAD and not all those with SAD have high levels of BI (Ollendick and Hirshfield-Becker, 2002), this trait has been strongly linked to SAD. For example, it has been found that highly inhibited 6-year-old children had significantly higher rates of SAD (Biederman et al., 2001), and BI is correlated with social anxiety symptoms in young adolescents (Muris et al., 1999) and college students (Mick and Telch, 1998). Using retrospective self- and mothers' reports (Hayward et al., 1998; Chronis-Tuscano et al., 2009), as well as prospective methods (Schwartz et al., 1999; Hirshfeld-Becker et al., 2007), investigators have found that high levels of BI earlier in life predicted the development of SAD later. Young children with high BI, compared with those with low BI, had a 3.15 times increased odds of developing SAD within 5 years after the temperament was detected (Hirshfeld-Becker et al., 2007). There is further evidence that BI is associated with a decreased risk for disruptive behavior disorders, and that there is no association between BI and other anxiety disorders (Biederman et al., 2001; Schwartz et al, 1999). However, other studies suggest that BI may be associated with longitudinal, concurrent, or parental risk for other disorders, such as specific phobias, avoidant disorder, panic disorder, other anxiety disorders, and depression (Biederman et al., 1990, 1993, 2001).

Anxiety Sensitivity

Anxiety sensitivity (AS) is another commonly researched tempermental factor and possible endophenotype candidate. AS refers to heightened sensitivity to the physiological experience of anxiety (Reiss et al., 1986). When individuals high in AS experience sensations such as heart racing, blushing, or sweaty palms, these sensations are noticed more quickly and perceived as more distressing, compared with individuals with low AS. People with SAD and other anxiety disorders tend to display greater AS, which may contribute to both the etiology and maintenance of SAD. For example, someone with high AS may interpret their own nonpathological reactions to early social experiences (e.g., nervousness on the first day of school) as more unpleasant, leading to discomfort in social situations. AS also contributes to avoidance of anxiety-provoking situations, which has been consistently identified as a maintaining factor in SAD (e.g., Rapee and Heimberg, 1997).

Parental Influence

Children are more likely to develop SAD if they have anxious or depressed parents (Lieb et al., 2000; Mancini et al., 1996), and parental influence on the etiology of SAD is not limited to genetics. Parents may contribute to the development of SAD in a variety of ways, and a number of trends emerge in the ways socially anxious people describe their parents (Ollendick and Hirshfield-Becker, 2002). For example, parents of socially anxious individuals tend to display lower affection and are more likely to be both overprotective and rejecting of their children. They are also more likely to use shame as a punishment technique. Parents who provide negative evaluation of social performance, especially when it is coupled with punishment, teach children that social mishaps and social situations in general are associated with risk. Some researchers have hypothesized that early life experiences of repeated criticism and rejection by parents may sensitize children to worries about negative social evaluation (Bruch et al., 1989; Ollendick and Hirshfield-Becker, 2002).

Parents, caregivers, and teachers may also increase a child's risk for SAD by overemphasizing the importance of gaining others' approval and maintaining very high standards for social interaction – values underlying cognitive models of SAD (e.g., Hofmann, 2007). In addition, parents who themselves have substantial social-evaluative fear are more likely to display avoidant or anxious behavior around socializing, allowing their children to pick up maladaptive habits through modeling.

What remains unclear in discussions of parental influence is whether parenting styles create anxious children, whether anxious children elicit certain types of responses from caregivers, or whether children and caregivers mutually influence each other. Well-meaning parents may at some

point worsen the cycle of avoidance in socially anxious children by accommodating their behavior. For example, a sympathetic parent may let a child miss school due to anxiety, or speak up on his behalf when he is tongue-tied. A desire to alleviate children's social distress may be even higher in parents who themselves have experience with SAD.

Sensitizing Events

SAD may be catalyzed by chronic or acute sensitizing events. In fact, some studies suggest that about half of all socially anxious people describe their anxiety as traceable to a specific highly embarrassing situation (Öst, 1985; Stemberger et al., 1995). In contrast, another study found that just 15% of socially anxious participants believed their anxiety came from a specific event, and many people experienced humiliating events without developing SAD (Hofmann et al., 1995a). Thus, further research is required to identify the contextual factors responsible for determining whether or not an aversive social event will precipitate SAD.

In the case of chronic sensitizing events, an individual may experience repeated negative social feedback (e.g., bullying, criticism from parents when speaking in public) such that some or most social situations become associated with negative outcomes (Beidel and Turner, 2007). Alternatively, an individual may endure a single humiliating social event that is experienced as highly aversive, leading to fear and avoidance of a similar outcome in the future. It is less common, but also possible to develop SAD after witnessing another person undergo social humiliation (Öst, 1985), known as vicarious conditioning.

Unfortunately, it may only take one or two sensitizing events to contribute to a self-perpetuating cycle of social rejection, withdrawal, and anxiety. Children who have negative social experiences are likely to withdraw, and withdrawn children are more likely to be rejected by their peers, leading to a greater incidence of further negative social experiences.

Cognitive Factors

In recent years, research has focused on identifying and treating cognitive biases characteristic of anxiety disorders. Among the most important cognitive biases displayed by individuals with SAD are *attention bias* and *interpretation bias* (Heinrichs and Hofmann, 2001). *Attention bias* refers to the fact that socially anxious individuals are likely to notice negative social information (e.g., an audience member yawning during a talk) compared with positive social information (e.g., the same person smiling later). *Interpretation bias* reflects the tendency of socially anxious individuals to interpret ambiguous social cues as negative (e.g., believing that someone laughed at a comment out of derision rather than amusement).

Interpretation bias has been documented in young socially anxious children, who interpret ambiguous stories in a negative light (Bögels and Zigterman, 2000). In the specific example of *interpretation bias*, socially anxious children consistently rate their own social behavior more poorly than do other observers (Rapee, 1995). Cognitive biases in adults with SAD are well documented (Foa et al., 1996; Hofmann, 2004, 2007; Heinrichs and Hofmann, 2001) and recent clinical trials have attempted to modify cognitive biases as a treatment aim for SAD, with some success (e.g., Beard and Amir, 2008; see also Hallion and Ruscio, 2011; Beard et al., 2012). More generally, SAD may be maintained by *confirmation bias*, which is common in healthy populations and refers to people's tendency to seek out, notice, and remember information that is consistent with preexisting expectations (e.g., that one is unlikeable). An important question for future research is whether cognitive biases are a cause of SAD, a consequence of it, or both, and whether the specific biases change throughout life.

Adults with SAD show heightened self-focused attention in social situations and typically experience negative self-perception as a social object (Clark and Wells, 1995; Hofmann, 2007; Rapee and Heimberg, 1997). Adult SAD patients typically focus on their own thoughts, physical sensations, and behavior, and this is accompanied by self-scrutiny (Hirsch et al., 2003) and unfavorable images of the self that are interpreted as accurate (Hofmann and Heinrichs, 2003). When considering social situations, socially anxious individuals are more likely to picture themselves from the point of view of an observer (Hackmann et al., 1998). Directing attention away from the self, a challenge for people with SAD, has been shown to decrease both negative self-evaluation and anxiety (Wells and Papageorgiou, 1998; Hofmann et al., 2004a,b).

Negative self-perception as a social object, a critical aspect in contemporary theories of SAD may be more relevant in adult patients with SAD than in younger children who do not yet have a matured sense of self. Therefore, it is possible that temperamental and biological factors are more predominant in the expression of SAD in younger individuals, whereas self-perception, which is shaped by autobiographical, societal, sociodemographic, and cultural factors, may be relatively more predominant in adult individuals with SAD.

Summary and Conclusions

SAD is a prevalent and debilitating disorder that impairs an individual's functioning in social relationships, occupational performance, and other important areas of life. SAD can be expressed as a developmental disorder with varying prevalence and presentations across the lifespan. Different factors influence the expression of SAD from birth to adulthood. These factors include: genetic liability as demonstrated by family and molecular genetics studies; temperamental factors like behavioral inhibition, a childhood trait

characterized by avoidance and fear of novelty; physiological factors like AS, which contribute to the maintenance of anxiety symptoms by facilitating avoidance; parental influences, which can include parents' own psychopathology and/or enabling behaviors; sensitizing events such as particularly humiliating social experiences; and cognitive factors like *attention* and *interpretation biases*, which not only heighten the likelihood of feeling fear in social situations, but also perpetuate avoidance thereof. In sum, an individual is both a recipient and an agent in his or her interaction with factors associated with SAD. The resulting complex presentation varies among individuals. Taking a developmental perspective when confronted with each case would provide the clinician a well-rounded understanding of its idiosyncratic etiology and benefit treatment planning. Nevertheless, further work is needed to improve the diagnosis and classification of SAD. Future classification systems should integrate and utilize physiological, genetic, and cognitive factors contributing to SAD and related disorders.

Social Properties (Facts and Entities): Philosophical Aspects

David-Hillel Ruben, University of London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social ontology is the study of what kinds of things discourse and thought about society is committed to, in order to be true. The article considers various candidates: social entities, social properties (and hence social actions), social facts, and evaluates the case for the existence of things of each kind.

Several philosophical strategies are described that might permit escape from such commitment: elimination, replacement, and reduction. The likely success of these strategies is also evaluated. The article argues that the many problems besetting these strategies, especially that of reduction, strongly suggest the irreducible existence of things belonging to these kinds.

One area of philosophical concern, dating from the very beginning of philosophy itself, is ontology: what is there? or what kinds of things are there? Ontology is the philosophical study of what exists. Many questions about existence are straightforwardly empirical, and hence of no interest to the ontologist. Are there unicorns, wombats, or planets circling stars other than our Sun? Other existence questions are not empirical, and these are in the province of the ontologist. Are there any physical objects, ideas, forms, numbers, properties, sets, propositions, minds, concepts, a Deity, or social wholes? To answer these questions is to engage in producing a list of the metaphysical kinds of things that one believes exist.

'Existence' in what sense? Some philosophers have held that each metaphysically different kind of thing exists in its own, special sense of 'existence,' or they may distinguish between being, existence, subsistence, and so on. A more plausible view is that 'existence' is univocal, that whatever exists, exists in the same sense, and that differences in the 'mode' of existence, say, of mind and body (if such there be), arise not because existence differs in the two cases but because of the differences between minds and bodies themselves. Bodies have a spatial 'mode' of existence, it might be thought, and minds do not, but, if so, that is because of the differences between them, not because they exist in different senses of that word. Besides, if existence had a special sense for each metaphysical kind of thing, ontology could become somewhat trivial. To the question of whether, say, propositions really exist, it would be anodyne simply to say that they do exist, but only in the special proposition sense of existence; that minds exist, but only in the special mental sense of existence; or that possibilia subsist rather than exist (since that is what possible things do), whereas actual things exist rather than subsist. Ontology would entail no honest labor, and therefore no real rewards.

All thought and all discourse presuppose the existence of certain things in order for at least some part of that thought or discourse to be true. When we speak, indeed even whenever we simply think, we typically take ourselves to be speaking or thinking about various things and ascribing certain properties to them. These entities can be concrete objects, properties, events, processes, or abstract objects (to name but a few candidates). It is not easy to capture this notion of aboutness (see Goodman, 1961), but I rely on the readers' intuitive grasp of the idea. Let us call whatever I think or speak about 'entities,' and whatever I ascribe to them 'properties.' Introduced in this way, these are very broad notions, especially that of a property, but there is no reason to limit the idea of a property more carefully in this context.

Are there, ontologically speaking, properties as well as entities? There are at least two ways in which to handle this question. First, there is the austere point of view that says that ascribing properties is not sufficient to be ontologically committed to them. There are properties, on the austere view, only if we talk or think about them, refer to them, and such talk or thought cannot be eliminated or replaced by other talk or thought that makes no such ontological commitment (see Quine, 1963). On this austere view, in the sentence 'The table is white,' we refer to the table but not to the color white or to whiteness, so no ontological commitment to whiteness is made by such a sentence.

There are, however, cases in which we do appear to refer to properties, even on the austere view: for exmaple (1) 'The color crimson is a shade of the color red.' It is easy to show that (2) 'The set of crimson things is a subset of the set of red things' will not do as a replacement for (1). If no such replacement or elimination is possible, then there are some properties, on the austere view.

Second, there is the more relaxed approach, which says that we are ontologically committed to properties if they are actually instantiated (or perhaps even if only well defined), whether or not we refer to them or talk about them. Ascription alone, without reference, may still involve us in ontological commitment on the relaxed view. If so, then even 'The table is white,' which ascribes the property of being white to the table, but does not refer to that property, commits us to the property of being white as well as to the table, since the sentence, if true, insures that whiteness has at least one actual instance.

Facts are of a more recent provenance. There appear to be singular facts, like the fact that some entity has some property, general facts, like the fact that whatever has one property also has another, and facts of identity (this list is not necessarily exhaustive). Are there really such things as facts? If there are facts, are they merely true propositions or are they anchored in the world itself? Philosophical views about the nature of facts

range from the wordy (or conceptual) to the worldly about their nature, and from the skeptical to the realist about their existence, without there being any philosophical consensus on either their existence or their nature. Facts have been enlisted for many purposes, one such being a correspondence theory of truth, and another being causal analysis. Are sentences true when they correspond to the facts? Is it the fact that the match was struck that caused it to light? These two particular uses of facts have come in for some serious criticism. Even so, there may well be facts, even if they were useless in theories of truth and for analyses of causality.

Ontological Commitments and Three Ways to Wriggle Out of Them

Sometimes, the apparent ontological commitments we have when we speak or think about things turn out to be only apparent. We do not always have to take our apparent ontological commitments seriously. This can happen in several different ways, three of which I want to describe.

First, I can make genuine mistakes, for example, when I take myself to be thinking about something that does not in fact exist or attributing to something a property it does not in fact have: Atlantis, Vulcan, the ether, or being a witch. These are cases in which we really are intending to speak about something, or say something about it, but fail. Let us call these sorts of cases, 'cases of elimination.' There simply are no such things or nothing really has the property in question (there is such a property as the property of being a witch, but nothing really has that property), and if we have at first placed them on our list of what there is, or what things are like, on finding that they do not exist or are not like that, we remove or eliminate them from the ontological catalog. Some philosophers have said this about minds, or mental states or mental properties. In cases of elimination, nothing can be salvaged from talk about such things as it stands. Such talk is plain false (see Lycan and Pappas, 1972).

Second, there are cases that, on first appearance, seem to be ones in which I am speaking or thinking about something, but closer inspection dispels the appearance. Not all cases of apparently thinking about something turn out, on analysis, really to be such. I may not be seriously intending to talk about the thing in question at all. Fictional discourse and metaphor provide two examples of this. If Romeo said that Juliet was the sun, it would be churlish to accuse him of uttering a falsehood on the grounds that she is not a heavenly body. (Of course Romeo and Juliet do not exist anyway, so are fictional, as they are only characters in a play.) A different example, more relevant for social science, for example, is talk about the average family, or the stakes being high in deciding some question, but such talk or thought is not really about what it might seem to be about. There is no such thing or things as the average family or as high stakes.

Average-family talk or thought is merely shorthand for talking about the number of people in the country divided by the number of households (or something like this anyway). Talk about the stakes being high is merely a way of talking about the important consequences of some decision. There is no such thing as the average family, or as high stakes, nothing that should be taken ontologically seriously, beyond taking seriously households and important consequences. These expressions are, as it were, just a façon de parler.

Let us call these last two examples, 'cases of replacement.' (How one is to deal with fiction or metaphor is far trickier.) The original talk, r_1 ('the average family,' 'high stakes'), superficially has ontological commitments of some sort. The replacing talk, r_2 ('households' and 'important consequences'), does not have those same apparent ontological commitments (although of course it has some of its own). The burden of proof, in such cases, falls on the person wishing to show that some of the ontological commitments of the original talk are apparent but not real. He or she must indicate the replacing talk that lacks them. In these cases, our original talk gets salvaged, because it is true, if the replacing sentence without the same apparent ontological commitments is true.

Third, there are cases in which our talk or thought really and not just apparently is about some entities, but they turn out not to be sui generis, since they can be reductively identified as or with another thing. These are, appropriately, cases of reductive identification. These might be examples of the sort of reductive identification that claims so much of philosophers' energies. There are, it may be said, physical objects, but they are really only sets of sense data; there are mental states, but they are identical with brain states; there are numbers, but they are merely the same as sets of sets; there are properties, but they are nothing more than sets of similar objects. Facts might just be true propositions. Such attempts at reductive identification allow the philosophical cake to be both had and eaten. Along with common sense, it can be asserted that there are such things. However, along with some ideal of philosophical acceptability, they can be reductively identified with another thing after all.

Insofar as philosophical reductive identification succeeds, it allows us to shorten our ontological list, while not denying the claims of common sense. It is for this reason that the term 'reductive' is appropriate; these identifications permit a reduction in the number of basic ontological commitments. On a physicalist reductive analysis, for example, there are mental states, or mental properties, but they do not have to be taken ontologically seriously, beyond taking bodily or brain states or properties seriously. According to Berkeleyian idealism, there are tables, chairs, and so on, but they are only ideas in the mind. Once ideas in the mind are on the ontological list, adding tables and chairs would be superfluous. Tables and chairs are already on the list, if ideas in the mind are and that is 'all' they are.

Again, in cases of reductive identification, our talk gets salvaged, since the original talk is true if the analysis containing the reductive identifier is (*see* Rational Choice Explanation: Philosophical Aspects).

Some Issues in Social Ontology

In this article, we are interested not in ontology in general but in some issues of social ontology in particular. Thought and discourse about society, whether lay or by the social scientist, raises these ontological questions too. In social thought and discourse, we appear to be speaking at least sometimes about social objects, social events, social process, social properties,

and social facts. However, as we saw for the general case above, it is one thing to admit that there are apparently such entities as France, the United Nations, and the Icelandic working class; social properties such as the property of being a mayor, being a charter member of the United Nations, or being an alter; or events like World War II or the Great Depression, but quite another to insist that they comprise a world of sui generis social objects, events, or properties, or whatever, and that they cannot be either eliminated or replaced or reductively identified with something more physically or psychologically respectable.

Often, the positions described in the relevant literature about social ontology are posed in terms of individualism and holism, sometimes with the qualifying adjective 'methodological' added. Sometimes, the positions are expressed in terms of facts; at other times, in terms of entities. Supervenience claims for the social ('the social supervenes on the nonsocial') are sometimes posed in terms of facts, at other times in terms of properties. It might be claimed that there are no irreducible social facts, that there are no irreducible social entities, or that there are no irreducible social properties. These claims are not equivalent. Rarely, if at all, is the distinction drawn in the relevant literature between the existence of social entities, social properties, and social facts. Does individualism in the social sciences eschew social entities but admit irreducible social properties? Should it eschew both? What should it say about facts? Might there be distinct versions of individualism, so that it comes in stronger and weaker forms?

I have already given or will give examples of social objects (Quinton, 1975–6), properties (Ruben, 1985), and facts (Gilbert, 1989). We are committed to these, unless we can show that these turn out to be cases in which we can, without loss, eliminate discourse about them entirely or replace such talk with other talk that makes no similar ontological commitment, or for which there is some reductive identification available.

What does 'social' connote? The basic application of the term relates to properties. What makes a property a social property? This is, I think, a difficult question. Some entity's having a property may have a social cause or social effect, without making the property itself social. For example, the soil's being eroded may be caused by inept bureaucracy, and may result in a stock market plunge, but none of that makes the property of being eroded a social property. Whether a property is social depends on something about the property itself, and not on the causes or effects of its being instantiated.

A property is social (roughly, without some refinements unnecessary here) if and only if from the fact that it is instantiated, it follows that at least two people exist and have an interlocking system of beliefs and expectations about one another's thoughts or actions (Ruben, 1985). Intuitively, I think this gets our idea of sociality about right, although one might just think that the requisite number should be greater than two. For example, the property of jointly carrying a stone is not social on this account, and rightly so, because two people might jointly carry the stone without either being aware of what the other was doing, oblivious to each other's very existence. Jointly carrying requires two people, but makes no necessary demands on their beliefs and expectations about one another. Purchasing a stone is, on the other hand, a social property on this account, and rightly so. No two people could be engaged in such a transaction without having a whole host of beliefs and expectations about the actions of the other.

Social entities, if such there be, are entities such that they have at least one social property essentially. France, for example, is essentially a nation; the Icelandic working class is essentially a class, a working class, and Icelandic.

No discussion of social ontology could be complete unless it brought to the fore actions and social events (including processes and states) as well, and in particular social actions (*see* Joint Action and Collective Action). Once the idea of a social property is to hand, we can use it to introduce the idea of sociality as applied to these other social ontological categories as well. For example, armed with a preexisting concept of change, a social event can be thought of as a change of any sort occurring to a social entity (e.g., France's increase in population) or a change in which a nonsocial object looses or gains a social property (e.g., Fiorello LaGuardia becoming mayor of New York). In a similar manner, a social fact could be either the fact that some social entity has, loses, or gains some property or the fact that some nonsocial object has, loses, or gains some social property (and we can add to this for whatever other kinds of facts there might be). So our idea of the social fans outwards, as it were, from our idea of a social property to other social ontological categories.

Social entities, if such there be, are never concrete, in the way in which earlier examples of entities were. Concrete entities, like Socrates and the tallest building in New York, are exclusive space occupiers, no two of which can occupy the same space at the same time.

Social entities, in general, are space occupiers; France occupies a certain region of physical space, and the Icelandic working class is physically in Iceland. However, social entities are not exclusive space occupiers. Suppose a diocese of the Catholic Church, call it 'Sancta Gallia,' occupies exactly the same geographical area as does France. It could even be that all and only French people were members of the diocese. If so, two distinct social entities, France and Sancta Gallia, would occupy the same physical space at the same time and have identical memberships. However, France $\neq$ Sancta Gallia.

What, then, of the three options we have available, for dealing with these apparent ontological commitments of our social discourse? Elimination of discourse about social entities would seem to involve an intellectual loss; we could not even in principle say things we would want to say without the discourse. (Imagine where we would be without sociology, history, anthropology, and a part of economics, for example.) The issue here is not just one of linguistic economy. It is not that we could not nearly as easily say what we want without social discourse but could only do so in an altogether more baroque fashion; rather, the claim is that we would have no way in principle of conveying what we want to say without that social discourse.

On the other hand, replacement does seem possible for some very simple and atypical examples. Another case that has been mentioned in the literature is 'The Jewish race is cohesive,' which appears to commit the speaker or thinker to an entity, the Jewish race. However, it is alleged, this is replaceable by 'Jews tend to marry other Jews,' and so on, and the latter makes no such ontological commitment to the existence of a race. 'The Jewish race is cohesive' behaves very much like 'The average

family has 3.2 members.' (See J.W.N. Watkins, 'Ideal Types and Historical Explanation' and 'Historical Explanation in the Social Sciences,' the first of which is reprinted in Ryan (1973), and both of which are reprinted in O'Neill (1973).) In this last example, the replacement does eliminate reference to such an entity as a race, but it is hardly a good example of the replacement of the social by the nonsocial more generally, since the property of being Jewish is (arguably) itself a social property.

I do not wish to claim that these replacements are never available; perhaps they do work for the case just mentioned. However, they are atypical, and it seems hard to see what replacement strategy would work for most other examples of social ontological commitment. What seems clear is that most talk or discourse about society is neither like talk about average families nor like talk of high stakes or like talk about the Jewish race, and hence are not candidates for a replacement strategy. Consider 'France is a charter member of the United Nations.' What sentence or sentences could replace this, yet convey the same information, at least in the sense of having the same truth value, and yet make no ontic commitments to a nation state and a world organization, or anyway to something else that is itself social? I can here only invite the reader to suggest candidates; I myself know of none. Replacement does not work as a general strategy for the social.

However, it is one thing to admit that there are such entities as France, the United Nations, and the Icelandic working class, or social properties like being a mayor or being an alter, and that they can neither be eliminated nor replaced, but quite another to insist that they comprise a world of sui generis social objects, events, or properties and cannot be reductively identified with something nonsocial, something more physically or psychologically respectable.

Many philosophers are drawn to the sort of reductive strategies that I mentioned above (Mellor, 1982). So various reductive strategies suggest themselves for social entities: France is (merely) a geographical area or a set of persons, and so on. No one can 'prove' that no reductive strategy could work. (It is not very easy to prove a negative existential claim.) What must be done, I think, is to evaluate each reductive strategy that suggests itself, one by one. My view is that no reductive strategy for social entities or social properties proves successful.

There are some general lessons one can draw, however, from the failures. The vague thought, 'Nations are identical with the people who make them up,' is ill-formed. In any reductive identification, names or definite descriptions must flank both sides of the identity sign. Therefore, for instance, 'France = ….' Well, identical to what? Candidates to occupy the space on the right-hand side of the identity sign will either be extensional or nonextensional entities, in the following sense. Sets and aggregates and landmasses are extensional, since, if a and b are sets or aggregates or landmasses, $a = b$ if and only if a and b have exactly the same members, components, or parts.

No extensional entity in this sense could be identical with France, for example, since their identity conditions will differ. France can remain numerically one and the same, in spite of variation in its citizenry, residents, or land occupancy. Even if one considered the set of all the actual citizens of France past, present, and future, or pieces of land that France ever occupied at any time, past, present, and future, there would be modal differences.

France could have occupied a different piece of land than it did, or had different citizens or residents than it did, but this could not be true of the set or aggregate of its citizens, residents, or lands. France is nonextensional; sets, aggregates, and landmasses are extensional, and no nonextensional entity could be identical with an extensional one. (In fact, this little argument that relies on modal differences assumes that 'France' and 'the set of …' both rigidly designate, since the identity required is identity across all possible worlds. I would argue that this assumption is true.)

If France is a nonextensional entity and no nonextensional entity can be identical with an extensional one, then what about some nonextensional entity for the reductive identification of France? Examples that come to mind are things like groups. Is France to be identified with the group of French people? The problem with this suggestion is that a group (in the relevant sense) seems itself to be a social entity, and hence hardly a candidate for the reductive identification of France with a nonsocial entity. What the determined reductivist of the social to the nonsocial needs to find is a nonextensional entity that is also nonsocial, for the reductive identification of France, and I am aware of no such obvious candidate.

What sorts of properties are ascribed to things when we think or talk socially? We can think or speak of either social entities or nonsocial ones like Socrates or the tallest building in New York and, in either case, ascribe social properties to them: 'France is a charter member of the United Nations' ascribes to a pair of social entities, France and the United Nations, the relational social property of being a charter member of; 'Socrates was a prisoner in Athens' ascribes to a nonsocial entity, Socrates, the relational social property of being a prisoner in.

The relational social property, being the mayor of, certainly figures in 'Fiorello LaGuardia was mayor of New York,' so on the relaxed view, we are committed to the existence of social properties. However, the sentence is not about that social property. It is only about Fiorello LaGuardia and New York. Therefore, on the austere criterion of ontological commitment to properties, the sentence commits us only to the existence of a person and a city, but not to the existence of a social property.

Even were we to adopt the austere view, there are a host of arguments, modeled on ones about properties generally, which do move us to talking about social properties, and so to the existence of social properties. Here are two such arguments: (1) if Iceland is capitalist, and if France is capitalist, then there is at least one social property, being capitalist, that Iceland and France share; (2) if being a mayor was a role LaGuardia enjoyed, then it follows that there is at least one social property, being a mayor. The argument instanced in (1) and (2) parallels one by Putnam (1980) on properties generally.

We talk and think about social properties, and I do not see how we could simply eliminate, or do without, such discourse. Nor do I know of any discourse that could replace discourse about social properties, and that lacked the ontological commitment to social properties but allowed us to convey the same information or messages. Therefore, on both the austere and relaxed views about the existence of properties, there are social properties, as well as nonsocial ones.

However, we can still ask, could each social property be reductively identified either with some specific nonsocial property or with some Boolean construction of such (suppose the set

of nonsocial properties was closed under disjunction, conjunction, complementation, and quantification)? I doubt whether this could be so. Let me give an indication of why I think this.

Some social properties are both nonvariable and weak, in the following senses. A social property *P* is nonvariable if and only if *P* is instantiated, then some specific set *s* of interlocking beliefs and expectations exists. For example, the social property of participating in the custom of drinking tea at breakfast is nonvariable, since the beliefs and expectations necessarily associated with it must be the set of beliefs and expectations about drinking tea at breakfast. A social property *P* is weak if and only if *P* is instantiated, then the interlocking beliefs and expectations are about types of events that are not themselves social. The social property of participating in the custom of drinking tea at breakfast is weak as well as nonvariable, since the beliefs and expectations associated with it concern drinking tea at breakfast, which is a nonsocial property. Since it does not follow from the fact that the property of tea drinking at breakfast is instantiated that atleast two people exist.

However, the most characteristic sorts of social property are neither nonvariable nor weak; they are variable and strong. Consider the property of being a mayor. If that property is instantiated, it is true that some set of interlocking beliefs and expectations must exist, but there is no one particular set that must exist. There is an indefinitely wide range of things that a mayor might be expected to do in various different societies or social settings. Therefore, the property is variable, in the sense of being indefinitely or infinitely variably realizable by many different sets of interlocking beliefs and expectations. (Whether a property could be reductively identified with a property that was itself an infinite disjunction of properties is an open philosophical question.) Moreover, the property is strong, since what a mayor is expected to do involves events and activities like receiving the ceremonial key to the city, opening formal events, representing the city at certain social or political functions, and so on, and these things are themselves social events or activities.

It seems to me that these two features of typically social properties make the reductive identification of social properties with nonsocial ones exceedingly implausible. One might have thought that a social property could be reductively identified with the nested and interlocking set of beliefs and expectations with which it is associated. However, since there is an indefinitely long list of such sets associated with each typically social property, and the contents of these beliefs and expectations themselves require the existence of further social events or activities, the reductive identification appears to fail.

Thus far, I have thought of reductive identification as being the obvious strategy for the individualist about the social, who rejects elimination and replacement, but two additional strategies should be mentioned. First, supervenience was once thought to offer an attractive alternative to reductive identification for the individualist. A set of *S* (say, social) properties was said to supervene on a set of *P* (say, nonsocial) properties just in case, for any two objects, there could be no difference in their *S* properties unless there was a difference in their *P* properties. Sameness of two things in respect of their *P* properties entails sameness of the two things in respect of their *S* properties. The thought was that supervenience would tie the social down to the nonsocial in a nonreductive way that would still appeal to an individualist about the social.

A version of supervenience called either 'global supervenience' or 'regional supervenience' was thought to be especially suitable for the case of social properties (Currie, 1984; Pettit and List, 2011). The property of being a coin worth £1 did not supervene just on that single coin's physical properties but would have to include the physical properties of many other things as well, for example, whatever the physical properties were of the banks and other institutions necessary for there being coinage, monetary value, and so on.

The idea was meant to be that supervenience could provide an alternative to reductive identity, which was thought to be too strong a demand to place on the relation of the social to the individual, but would still provide a strong enough relation to 'tie' the social down to the individual and hence could count as some legitimate form of individualism. That hope has proved to be elusive. The notion of supervenience described above is too weak; it entails at most the covariance of social and nonsocial properties and goes no way in capturing the individualist's intuition that the social depends on the nonsocial in some way in which the nonsocial does not depend equally on the social. Accounts of supervenience strong enough to capture the idea of the dependence of the social on the nonsocial and that tie the social down to the individual seem to collapse back into reductive identity; accounts of supervenience weak enough to escape the collapse into reductive identity are not strong enough to tie the social down to the individual in the desired way. Supervenience seems not to be able to do what was expected of it, an account of nonreductive individualism in the social sciences (see the essays in Savellos and Yalçin, 1995).

Finally, the idea that social entities are wholes, whose parts are individual persons, has often appealed to those with an individualist agenda. It is not obvious why this should count as a type of individualistic doctrine, as it is purported to be, unless one adds the thought that a whole is no more than the sum of its parts. The plausibility of this doctrine relies, in any case, on assuming that the standard logic of wholes and parts, mereology, would carry over to our understanding of social wholes and their parts. The analogy is specious. The relation of an individual to the social 'whole' of which it is said to be a part is quite unlike that of the relation of a part to a genuinely mereological whole. Here is one difference. In the case of a part and the mereological whole to which it belongs, the idea of a part is transitive: if *a* is a part of *b* and *b* is a part of *c*, then it follows that *a* is a part of *c*. The social case is not transitive: if a person is a member of a club and the club is a member of an organization of clubs, it does not follow that the person is also a member of the organization of clubs. The mereological relation of parthood and the social relation of membership behave quite differently logically and the clarity and precision of the former cannot be used to elucidate the latter. If we cannot use the mereological ideas of whole and part for the social case, it is quite unclear what the meanings of 'whole' and 'part' are in their purportedly social usage.

The overall lesson in this discussion, I submit, is that these terms, 'holism' and 'individualism', do not name unambiguous positions unless and until various distinctions are drawn, and the ontological claims of each position are clearly specified. (See S. Lukes, 'Methodological Individualism Reconsidered,' reprinted in Ryan (1973).)

Abstract

Ordinary people have often confronted more powerful opponents expressing their grievances and demands for restitution. The forms or types of collective actions taken vary widely, ranging from more conventional strategies of political persuasion such as petitioning and legal demonstrations, to more disruptive tactics such as strikes, sit-ins, and occupations, to more violent acts that inflict material and economic damage and loss of life. Just as societies have transformed over time the forms of social protest have changed over time. Social protest from our earliest history to today is a potent and effective motor for social change.

From the year 1040 to well into the 1100s, women in western Sweden fought against the Cistercian Order's Christian evangelizing efforts. Women carried out their social protests employing imaginative strategies of disobedience, entering Varnhem's Abbey dancing and defecating on the altar. Their persistent social protests generated considerable correspondence between the monks and the sitting Popes, lamenting over the difficulties they faced in their encounters with the rebellious Scandinavian women. On 16 December 1773, after officials in Boston refused to return three shiploads of taxed tea to Britain, a group of colonists boarded the ships and destroyed the tea by throwing it into Boston Harbor, what came to be known later as the Boston Tea Party. The social protest by the 'Sons of Liberty' has become an iconic event in American history. These examples of social protest remind us that social protest has been with us since the dawn of history. Ordinary people have often confronted more powerful opponents expressing their grievances and demands for restitution. Acts of social protest are acts of contention by people who lack the resources on their own to bring about social changes. In short, social protest is contentious collective action. In the nineteenth century social protests became increasingly organized and coordinated. The first international May Day demonstrations in 1890 were widely celebrated across Europe and continue to do so to this day. May Day demonstrations were the 1-day each-year events globally when organized labor could present its goals to the public; an 8-h workday was the first concrete demand, later in the 1890s to be supplemented by improved working conditions, universal suffrage, peace among nations, and international solidarity. The latter decades of the twentieth century witnessed a resurgence of social protests and widespread civil unrest. In August 1965, a questionable arrest of a black man in Los Angeles, California, triggered a 6-day civil disturbance. What has become commonly known as the "Watts Riot" resulted in 34 deaths, 1032 injuries, 3438 arrests, and over $40 million in property damages. Researchers found that a significant percentage of the white population surveyed in Los Angeles after the event defined the riot as an act of social protest against prejudice and discrimination against the black population (Jeffries et al., 1971). Social protests in Paris during May 1968 commenced with a series of student occupations and strikes that broke out at a number of universities and lyceés in Paris, following confrontations with university administrators and the police. The de Gaulle administration's attempts to quell those strikes by police action only inflamed the situation further, leading to street battles with the police – barricades were erected, cobblestones and Molotov cocktails flew through the air. The student protests were followed by the first wildcat general strike ever in France, which involved 11 000 000 workers, over 22% of the total population. The social protests reached such an extent of scope and intensity that government leaders feared civil war or revolution. However, when new elections were held in June, the Gaullist party emerged even stronger than before. This was the revolution that never was, in contrast to the Arab Spring. In 2011, massive social protests against authoritarian regimes swept across North Africa and the Middle East. The unexpected revolutionary events of the Arab Spring led to the overthrow of the regimes in Tunisia, Egypt, and Libya. After the so-called silent revolutions in Eastern Europe and the Soviet Union during 1989–91 coordinated social protests in authoritarian and semiauthoritarian regimes have emerged in former Soviet states, and most recently in North Africa and the Middle East. From the 1990s onward, transnational social protests with widened scopes of contention have increasingly appeared. More and more groups have engaged in social protest, not least we saw a dramatic increase in far-right antiimmigrant protests. A German neo-Nazi group calling themselves 'Die Unsterblichen' (The Immortals) orchestrated flash mob protests in cities all over Germany during spring 2011. In a social protest demonstration on 1 May in Bauzen, Germany, hundreds of black-clad figures with white masks suddenly converged in a street carrying torches and signs with extreme nationalist slogans, then dissipated before a major police presence could arrive. On 1 August 2012 the British Defense League and the Swedish Defense League joined forces in an act of social protest in Stockholm against what they called the 'islamization of western societies'. Their rally was met with an even larger number of counterprotesters in an act of social protest against the presence of right-wing extremists in the streets of Stockholm.

Social protests are collective acts of defiance. Social protest can be either violent or peaceful, dramatic or more routine. Social protest can include even what many would call unsavory demands, for example, the expulsion of immigrants. Acts of social protest can be more or less spontaneous and short-lived and acts of social protest can also be coordinated and sustained over time. This small selection of examples of social protest highlights that we are confronted with definitional and

situational problems. What is the historical legacy of social protest? How can we delineate social protest from social movements; social protest in relation to political protest; social protest in relation to major civil unrest or riots; and last, social protest in relation to revolutions?

Social Protest Defined

Ralph Turner (1969) defined an act of social protest as including all of the following elements:

> [t]he action expresses a grievance, a conviction of wrong or injustice; the protesters are unable to correct the condition directly by their own efforts; the action is intended to draw attention to the grievances; the action is further meant to provoke ameliorative steps by some target group; and the protesters depend upon some combination of sympathy and fear to move the target group in their behalf.
> (p. 816)

Turner calls our attention to social protest as an act of expressing grievances. Social protest is collective action that is meant to both call attention to grievances and seeks to confront authorities to take steps to address their grievances. If we break down the constituents included in the act of social protest we can delineate four elements. First, social protest is intentional and purposeful collective action. Second, social protest is a resource employed to signal protesters' concerns or grievances. Third, social protest is a form through which groups challenge authorities (Gamson, 1975), as such social protest is political performance. And last, social protests are the means toward achieving redressal of grievances.

The 'Political' in Social Protest

William A. Gamson (1975) in his classic work *Strategy of Social Protest* defined the groups that engage in social protest as an excluded group "seeking the mobilization of an unmobilized constituency … against an antagonist (lying) outside of its constituency" (pp. 16–17). Gamson's definition emphasizes that it is the disenfranchised that engage in social protest. Similarly, Francis Fox Piven and Richard Cloward (1977) argue that social protest is rooted in political exclusion and attempts to renegotiate the terms of political access in order to address grievances. Subsequently, social protest is inherently a political act, which seeks to implicitly lay its claim for political representation in a situation where the state regulates the political environment. While social protest is implicitly a claim for political representation, the collective action is enacted outside of the conventional channels of political representation. This is the element of protest in the conceptual duality of social protest. Social protest challenges state authorities to take political action on behalf of the protesters – social protest is political protest.

Who Protests

Which are those that engage in social protest? Classically, social protest was the sole means for subjugated groups to voice their concerns and demand restitution. Historically, it was slaves, peasants, laborers and crofters, women, the poor and disadvantaged, Black people in America, unemployed, religious minorities – the list is long – who, often in alliance with more powerful groups, engaged in acts of social protest. However, this story must be updated. David Meyer and Sidney Tarrow (1998) have proclaimed that in Western societies social protest has become so common and sponsored by increasing numbers and so many types of organizations that we can call them 'movement societies'. According to these authors, since the 1970s protest on the streets is no longer the sole prerogative of left parties or marginalized groups. The people who protest today are not necessarily the disenfranchised. On the contrary, particularly among those engaged in so-called new social movement politics, that is, the peace movement, environmental movement, women's movement, human rights movement, etc., we find a disproportionate number of well-educated, middle class professionals (Wallace and Jenkins, 1995). Furthermore, protesters today are not necessarily alienated from political institutions. Those who are more active in conventional politics are also more active in social protests. This development is not limited to Western democracies. For example, those who bore the brunt of social protests that brought down the Mubarak regime in Egypt 2011 were for the most part university-educated young people. Whereas in the past social protest was the means for the politically 'resource poor' to influence the polity, increasingly, the politically 'resource rich' are supplementing their political power potential with acts of social protest. Wide segments of the population are now engaging in acts of social protest.

Why Do People Protest

Social scientists at the *fin de siècle* regarded all social protest as deviant behavior, as irrational actions to be feared. This paradigm lived on well into the twentieth century where social protests were viewed as indicative of breakdowns or 'cracks' in the social fabric, and were alarming signs of felt grievances and discontent. By the 1970s, the theoretical focus had shifted from why people are aggrieved to why aggrieved people take part in social protest. Rather than explaining the irrational behavior of discontent, researchers now began to study the rational and instrumental aspects of why people protest. Why do people take the time and effort, and sometimes even the considerable risks, to participate in social protests?

In a classical study quantitative study of political protest in five Western democracies Barnes et al. (1979) that the among the standard social variables associated with a predisposition to protest, age, gender, and education mattered the most. The young, the better educated, and males were more likely to protest than the elderly, less educated and women.

Social psychologists investigate the motives behind protest participation and demonstrate that instrumental reasoning, identification, emotions, and ideological factors all come together to form a motivational constellation in response to the question as to why people protest (e.g., Klandermans, 1997). Bert Klandermans highlights three sets of motives, which inspire people to protest. First, we have the instrumental motive. People take part in a social protest in order to exert

influence, that is, to demand change for a perceived dissatisfaction or grievance. Second, a strong identification with a group enhances an individual's motivation to protest together with that group. Third, ideological motives for engaging in social protest include individual's search for meaning and most importantly their desire to publically express their views. Ideological motives are most often augmented by emotions, the affective component of ideology, for example, feelings of moral outrage over injustice. People are often led to social protest because they are angry and social protest provides them with the opportunity to voice to others those feelings. Klandermans emphasizes that all three sets of motives are more or less germane in understanding an individual's motives to participate in protest given that in some instances of protest one or two of the sets may be more important. For example, feelings of moral outrage can compensate for a situation where there is little hope of influencing change. However, he argues that we must consider all three sets of motives in some sort of juxtaposition in order to understand why people protest. Going beyond social psychological theories of protest, rational choice theorist Karl-Dieter Opp (2009) offers a model for accounting for social protests, which he calls a 'structural-cognitive model' in which he argues that structural factors and individual incentives mutually reinforce one another.

The 'Social' in Social Protest

Social protest brings people together for a common cause in concerted action, as such social protest is intrinsically social. The social processes of coming together, interacting to form common bonds, talking and assigning meaning to their actions are integral to social protest. The underlying precondition for social protest, as well as a consequence of protesting together with others, is the formation of a sense of 'we', a sense of being part of a collectivity in opposition to a jointly designated adversary. In order to understand how individuals and groups make sense of their protest actions we must grasp the processes through which a collective becomes a collective. Scholars within the so-called collective identity paradigm focus these social processes of collective protest. The late Alberto Melucci (1996), the leading theorist in this constructionist approach to social protest analysis, focused on how protesters define in cognitive terms the field of possibilities and limits they perceive while at the same time activating their relationships so as to give sense to their 'being together' in protest and to the goals they pursue. Melucci emphasized the emotional investments which enable individuals to feel like part of a common unity, a sense of we; desires and feelings, love and hate, trust and fear are all part of a body acting collectively. This is the underlying essence of the 'social' component in social protest.

The Forms of Social Protest

Demonstrations, strikes, occupations, vigils, mock funerals, marches and rallies, blockades, barricades, petitions, boycotts, cross-burnings, picket lines, canvassing, hunger strikes, riots, and guerilla theater, all come under the category of forms or types of social protest and are unconventional methods of political participation. The forms or types of collective actions taken vary widely, ranging from more conventional strategies of political persuasion such as petitioning and legal demonstrations, to more disruptive tactics such as strikes, sit-ins, and occupations, to more violent acts that inflict material and economic damage and loss of life. Sidney Tarrow (1998) differentiates three forms of protest actions: conventional, disruptive, and violent, acknowledging that contentious politics frequently combines all three elements. For example, a faction within a major peaceful demonstration can break out and occupy a square, while another faction can seek violent confrontation with the police. This is a common characteristic of large demonstrations today – their unpredictability. For example, the social protest demonstrations against austerity measures in Athens, Greece during 2011 most often led to violent riots between police and protesters.

We can also divide the forms of social protest between 'low-risk' actions and 'high-risk' actions. The latter are forms of protest that are illegal and the activists risk arrest, imprisonment, and/or bodily harm. High-risk forms of social protest run the gauntlet between nonviolent forms of civil disobedience and violent forms of protest, for example, riots, direct confrontations with adversaries, etc. While the vast majority of the forms of social protest are so-called low-risk actions, contemporary social protest often includes the more dramatic high-risk militant actions of small highly dedicated protest groups (Peterson, 2001).

Scholars use the concept of repertoires of contention to refer to the recurrent, predictable, and fairly narrow 'toolkit' of specific protest tactics used by a set of collective actors in a particular social protest (Tilly, 1995). However, even if tactical repertoires evolve slowly and protesters are more likely to select tactics with which they are familiar, innovations do come onto the scene. Sometimes, it is the novelty of the form of social protest, which can contribute to the success of the protest. For example, Doug McAdam (1988) shows that tactical innovations on the part of US civil rights activists such as sit-ins and freedom rides were effective because they caught authorities off guard. Innovations in the forms of social protest do not only catch authorities off guard, they also capture media attention spreading the messages of the protesters. Innovations are in short newsworthy.

The Historical Transformation of the Forms of Social Protest

The work of the late Charles Tilly (e.g., 1995) has made path-breaking contributions toward our understanding of the historical development of the forms of social protest. Tilly has introduced the notion of "repertoires of contention" which are historically situated "ways that people act together in pursuit of shared interests" (1995: p. 41). Sidney Tarrow (1998) emphasizes that repertoire is both a structural and a cultural concept, "involving not only what people *do* when they are engaged in conflict with others but what they *know how to do* and what others *expect* them to do" (p. 30, emphasis in original). Hence, repertoires are historically and contextually situated collections of forms of social protest. Just as societies have transformed over time the forms of social protest change over time.

Prior to the nineteenth century, social protests took the form of bread riots and grain seizures, peasant revolts that took the form of peasants brandishing pitchforks marching to 'occupy' land usurped by powerful landowners, religious rebellions, funeral riots, and so on. Social protest focused local issues and the forms of social protest were direct, often violent, and inspired by their claims. The traditional repertoire of contention was parochial and episodic in that the protest actions converged in a single community, the protesters took direct action that took particular forms that varied according to the issue pursued, the locality where the protest took place, and the group of people protesting (cf Tilly, 1995). For example, a group of hungry citizens could seize the grain from a merchant whom they thought was hoarding. The death of someone in the community could unleash a riot at the funeral. American colonists could parade with effigies of British authorities, and then burn the effigies.

During the nineteenth century, alongside of the older traditional forms of social protest new forms of social protest emerged that were more organized and engaged broader segments of the population, and that were more general and wider in scale. Compared with the traditional repertoire the new repertoire of contention, according to Tilly (1995), was cosmopolitan, modular, and autonomous, what he calls "modular collective action". The new forms of social protest were:

> *cosmopolitan* in often referring to interests and issues that spanned many localities or affected centers of power whose actions touched many localities. They were *modular* in being easily transferable from one setting or circumstance to another. … They were *autonomous* in beginning on the claimants' own initiative and establishing direct contact between claimants and nationally significant centers of power.
> (p. 46; emphasis in original)

The nineteenth century ushered in demonstrations, rallies, boycotts, strikes, and barricades and the nation-state became increasingly the target of the social protest. Social protest engaged wider segments of society, held together by new emerging forms of association and informal social networks. According to Sidney Tarrow (1998: pp. 43ff), informal networks underpinned the new emerging protest organizations and these networks were crucial for spreading the new forms of social protest. The expansion of the print media, together with growing literacy in Western societies, further helped diffuse the new forms of social protest.

During the nineteenth century, the rise of the modern state was supplemented with a new invention for social protest – the social movement. When social protests against powerful opponents are initiated, coordinated, and sustained we are confronted with this new invention of modernity. Not all social protests are part of a social movement. Tarrow (1998: p. 2) reserves the notion of social movement for sequences of social protest acts that are "based on underlying social networks and resonant collective action frames, and which develop the capacity to maintain sustained challenges against powerful opponents". Tarrow emphasizes that it is the capacity to sustain episodes of social protest that distinguishes social movements from earlier forms of contention. During the nineteenth century nationalist movements, labor movements, abolitionist movements, women's movements, temperance movements, and so forth, erupted on the national scenes throughout the Western world. Social protests became progressively organized in new ways that offered social protest stability and enhanced bases of power.

Social Movements

During the last 30 years, research on social movements has expanded prolifically and so also have the definitions of social movements legion. Snow et al. (2004, see for an excellent overview of social movement research perspectives) offer the following broad definition:

> social movements can be thought of as collectivities acting with some degree of organization and continuity outside of institutional or organizational channels for the purpose of challenging or defending extant authority, whether it is institutionally or culturally based, in the group, organization, society, culture, or world order of which they are a part.
> (p. 11)

Social movements share some of the key characteristics of social protest, that is, collective action outside of traditional institutional political channels that challenges authorities to take some action on behalf of the group. However, we cannot collapse the two binary concepts. Isolated incidents of social protest are not social movements. Only by sustaining collective action does an actor turn a contentious episode – a series of related and coordinated social protests – into a social movement. The key distinction between social movements and social protest is that the former is collective action sustained over time. Social protest is nevertheless a key, if not the key, element in social movements.

Contemporary Transnational Social Protest

We have seen a transformation of social protest from highly localized sites of protest to modernity's national scenes of protest. In this latter era, social protest was even coordinated and organized internationally. Abolitionists, women's suffragettes, peace activists, and not least the early labor movement activists met with their counterparts from other nations. The latter half of the nineteenth century saw a flora of international conferences that provided inspiration for the protest activists that participated. However, their social protest actions remained directed to their respective nation-states; they brought their grievances to their nation-states. We are witnessing today a new development in the scale and scope of social protest – social protest has gone increasingly global (see della Porta and Tarrow, 2005, for an excellent overview). This new form of transnational social protest is underpinned by the development of electronic media. The media spreads the influence of social movement actions and disseminates their messages within a mediated publicness where to paraphrase Todd Gitlin (1980), 'the whole world is watching' – simultaneously. Protesters today are more and more staging their actions as media events, the aesthetization of politics, in order to occupy this space of visibility which is both opening

and expanding in our historical epoch of what we can designate as media modernity (Peterson, 2001). The struggle to make oneself heard or seen is not a peripheral aspect of the social and political upheavals of the modern world; on the contrary, it is central to them. The struggle to capture the attention of media audiences is essential for an understanding of contemporary social protest. Alberto Melucci (1996) argues that collective action itself becomes a new medium and intervenes in the public discourse, the domain in which the words of protesters can be heard, by its interaction with the media system.

The global or planetary nature of mediated publicness in media modernity is revealed in the ability of media images and messages to act as a catalyst for action that spills well beyond the immediate locales in which events occur. Events taking place on the other side of the globe can serve as a rallying cry for the action mobilization of individuals and groups far removed from the spatial-temporal context in which these events initially occurred. The social protest event staged by 'Pussy Riot' in Moscow 2012, the subsequent arrest and conviction of three of the young women, gave rise to actions of social protest across the Western world.

The transnational environmental movement, understood in its broadest sense, offers us perhaps the clearest case of the widening scope of social protest. The environmentalist discourse has become increasingly couched in universal claims. Environmental degradation, it is asserted, is a problem that humankind faces in common. And indeed, thanks to industrialization and the spread of Western technologies across the globe, the physical threats to the environment are becoming more similar the world over. People throughout the world are finding themselves 'in the same boat', and this 'boat' is limited in that we have reached, and some would argue, overextended, the limits of our planetary system. Hence, green political thinkers have developed a rhetoric of globalism in order to promote and engender a process of planetary identification, challenging people to identify themselves as 'citizens of planet Earth' or as 'astronauts on spaceship Earth' rather than seeing themselves as citizens of some country, members of an ethnic group, comrades within a class. From the 1990s onward, environmental activists and governments alike see environmental issues as more often as not transcending national borders. Hence a new politics of environmentalism has been ushered in which transnational social protests direct their demands for redressal to both transnational political bodies and nation-states.

World Social Forums, the global environmental movement mentioned above, International Campaign to Ban Landmines (ICBL), are just some examples of social protest that are engaging protesters across the globe. While not neglecting their national contexts, these protesters are also challenging transnational authorities. Major demonstrations have been held in conjunction with, for example, economic summits, EU summit meetings, and global environmental summits. The global parameters of social protest mobilizations today have encouraged disparate groups and individuals to participate in mass demonstrations. Social protest groups, action networks, and individuals are increasingly pooling their resources in order to make their challenges heard and to reach their goals. Diversity is a major characteristic of contemporary social protest demonstrations, which are often described as multigenerational, multiethnic, multiclass, and multiissue. These temporary collective action mobilizations represent a broad spectrum of causes and goals. Participants represent a variety of issues and a wide diversity of targeted adversaries. The combination of groups and participants coming together creates a powerful impression and an impact, which is perhaps out of proportion with their individual strengths. The melding together of the various groups into one large body implies power, and attracts attention and publicity, which, in turn, draws more and more participants. Today, a single demonstration can (and most often does) include a cacophony of grievances expressed by a wide range of social protesters.

Social Protest and Revolutions

The cases of regime change in Eastern Europe in 1989 and the Soviet Union in 1991 were moments when weak states faced weak societies. While these countries more or less lacked civil societies from which social protest is traditionally mobilized, nevertheless massive social protests were launched against communist regimes in economic and political crisis. With the exception of Romania, nonviolent social protest toppled the regimes in Poland, Hungary, Czechoslovakia, and East Germany. Albert O. Hirschman (1993) employed his famous concepts 'exit and voice' to explain that while for nearly four decades exit had undermined voice in the German Democratic Republic the tumultuous events in 1989 led to a situation when many East Germans found the road back from exit and apathy to voice and public action (see also Opp et al., 1995). After a broad popular protest mobilization, on 11 March 1990 Lithuania became the first of the Soviet republics to declare its independence; Moscow first recognized this proclamation on September 1991 (following the abortive coup in Moscow). The remaining republics would take the Lithuanian example and one by one they declared their independence from the Soviet Union.

Color revolutions or Flower revolutions are the names that have been given to the protest mobilizations, which developed in postcommunist societies in Central and Eastern Europe after the year 2000. The mobilizations have used (mostly) nonviolent means to protest against governments seen as entrenched and authoritarian. In four successive countries, massive street protests followed disputed elections and led to the resignation or overthrow of leaders considered by their opponents to be repressive. They have adopted a color or flower as their symbol, which has embodied their nonviolent strategy.

While the peaceful revolution in Yugoslavia in 2000 did not adopt a color or specific symbol (aside from the clinched black fist), it is often referred to as a starting point for the color revolutions to come. The youth movement Otpar (Resistance) initiated a series of whistle blowing mass demonstrations in Belgrade, which led to the overthrow of Slobodan Miloseviç. Members of Opar have inspired and trained activists in related youth movements. The Centre for Applied Nonviolent Action and Strategies was founded in 2001 by some former Otpor members. This international nongovernmental organization has disseminated the lessons learned from their successful nonviolent social protests through scores of trainings and workshops for prodemocracy activists and others around the

world, including Georgia, Ukraine, Krygzstan, the Maldives, and Egypt. Forms of social protest can be transferred across borders, not only through media but also by direct contact with fellow protest activists.

The commonalities between these mobilizations of social protest were striking. In all of the countries, massive social protests followed disputed elections, which were the result of extensive grassroots campaigning and coalition building among the opposition. In all of the countries, youth resistance networks played a central brokering role as initiators and coordinators for the protests. Their participants used mostly nonviolent strategies to challenge the incumbent leaders. Another characteristic of the social protests was their simple straightforward message: the incumbent regime was evil and must be replaced.

Massive social protests, even in authoritarian or semi-authoritarian countries, can under favorable political circumstances give rise to revolutions. However, revolutions are not merely aggregates of social protest actions. Multiple centers of political authority are created transforming the conflict between challengers and members of the polity into a struggle for power. The ensuing conflict can then (at best) lead to a revolutionary outcome, which is the transfer of state power to new sets of actors. The examples of social protests mentioned above in some cases led to effective transfers of power, in others only partly successful revolutionary outcomes. However, in all of these cases of social protests demanding democracy and measures to come to terms with what was perceived as entrenched governmental corruption, the outcomes of the social protests were regime changes. Social protest is collective action that challenges authorities to redress their grievances; it is not by itself a bid for state power. Social protest in democratic contexts seeks most often policy reforms or group recognition. However, in authoritarian and semiauthoritarian contexts social protests can lead to revolutionary outcomes – political upheaval and the overthrow of regimes.

Conclusions

Social protest, the use of unconventional means of political persuasion, is a fundamental feature of democratic societies. Politics 'in the streets' is a necessary complement to parliamentary politics. And today – between elections – people are increasingly using this channel of political participation in order to make their voices heard. In nondemocratic countries, social protest emerges in the windows of opportunity that appear in even these societies. Activists seize these opportunities and stage social protest actions that have proven to be powerful enough to overthrow regimes. Social protest from our earliest history to today is a potent and effective motor for social change. Social protest witnesses the power of outsiders to influence the course of history.

Social Protest and New Media

Abstract

Digital media are helping people self-organize and coordinate massive protests in the absence of formal organizations. This is challenging old theories of collective action, and encouraging research on large-scale communication networks. This article gives an overview of digitally enabled protests, and assesses the evidence on how new media facilitate their spread and coordination.

Definition of Concepts

Protests are a form of collective action that emerge to influence the decisions of governments or organizations by means of direct action (Opp, 2009). Examples include demonstrations, petitions, boycotts, sit-ins, or street blockades. New media encompass a range of digital technologies that allow users to engage in social interactions on a global scale, and be exposed to information and behavior, often in real time. Digital technologies are facilitating new forms of protest like hacktivism, denial of service (DoS) attacks or flash mobs (Chadwick, 2006; Earl and Kimport, 2011). These protest tactics rely on decentralized networks that operate in the absence of hierarchical organizations, a feature that makes them more flexible and adaptable; however, the lack of formal organizational structures also means that protests are more transient and volatile. This article offers an overview of theories and findings about how social protests emerge in the digital age.

Changes in the Logic of Collective Action?

Some scholars argue that new media are changing the scale of protests, but not the mechanisms that make them grow. Digital technologies, the argument goes, allow protests to grow bigger and faster, as when petitions are signed by thousands of people in a matter of hours; but they still rely on the same building blocks, namely, individuals solving the trade-off of whether it is worthwhile to participate in the collective effort. An increasing number of researchers, however, suggest that new media are stirring deeper change and reconfiguring the logic of collective action; this, they argue, requires a change of theoretical model (Bennett and Segerberg, 2012; Bimber et al., 2005; Lupia and Sin, 2003). The following three sections offer an overview of the principles that define the classic approach to collective action (i.e., the individual-level assumptions on how people face the decision to join a protest); how individual decisions concatenate to generate the cascading behavior that often accompanies the emergence of protests (i.e., what underpins the critical mass associated to successful protest events); and how new media are changing behavior on these two levels (i.e., the level of individual decisions and the level of collective dynamics).

The Classic Approach to Collective Action

The starting point of all classic approaches to collective action is the social dilemma that often arises during the provision of public goods. Public goods are nonexcludable, that is, everybody can enjoy them once they exist, even if they did not contribute to their provision. The assumption of classic approaches is that actors are rational, that is, they behave in accordance to the costs and benefits of their actions. What goes in their best interest in the case of collective goods is to free-ride. However, if all actors think the same way, no public good is provided and everybody is worse off. What this dilemma captures, in brief, is that individual and collective interests often go in opposite directions. Classic approaches to collective action try to understand how this dilemma is solved.

The most influential approach in this classic tradition is *The Logic of Collective Action* by Mancur Olson (1965), published decades before the Internet and new media were so widespread and ubiquitous. Olson identified three key elements that help solve social dilemmas. The first two are sanctions and selective incentives, which are intended to modify the cost–benefit equation. Sanctions punish people who do not comply with the provision of public goods (i.e., participation in protests), and selective incentives are intended to stimulate rational individuals toward contribution. The third element is related to the size of the organizations providing those incentives: to enforce sanctions and apply selective incentives small groups function better than large groups because they make it easier to monitor how people behave and punish or reward them accordingly.

This approach is built on the assumption that individuals are driven by selfish motivations, and that we need to build a structure of incentives or punishments to redirect that selfish rationality toward collective goals. However, alternative approaches that relax these assumptions have also been proposed. Sociologists like Jon Elster emphasize normative behavior, or the role that social norms play as a motivational force that is irreducible to rationality (Elster, 1989). People feel compelled to cooperate because breaking that expectation of behavior generates feelings of shame. Norms of cooperation can actually emerge from long-term self-interest: social dilemmas are not isolated events, and selfish behavior is often penalized in future interactions, which invites actors to reconsider their free-riding inclination. These strategic and temporal

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95076-1

dynamics are modeled in another classic work, *The Evolution of Cooperation*, which shows that cooperation produces more benefits in the long run (Axelrod, 1984). These two alternative approaches highlight an important element that is missing in Olson's approach, namely that individual decisions are interdependent – people in the real world do not make their decisions in isolation, but placed in a social context where influence links their actions.

The Importance of Interdependent Decisions

Acknowledging the importance of interdependent decision-making has a crucial effect on how we conceptualize collective action. As with other collective phenomena, the patterns observed on the aggregate level (i.e., the number of people joining a protest) cannot be directly derived from the motivations at the individual level. In the book *Micromotives and Macrobehavior*, Schelling (1978) introduces the notion of a critical mass, that is, the point beyond which the chain reaction of people driving other people to join a protest becomes self-sustaining. Thermostats are often used as a metaphor of this type of process: they regulate the temperature in a room by registering changes and responding to them; in a similar fashion, the level of contributions to a social protest responds to the contributions registered, activating a feedback loop that – as with thermostats – can be positive (and bring the protests to success) or negative (and bring the protests to failure).

The interdependence of decisions creates networks of interaction that mediate the way in which feedback mechanisms unfold. Threshold models offer one of the most prominent theoretical approaches to these network dynamics (Granovetter, 1978; Granovetter and Soong, 1983). The notion of threshold refers to the intrinsic propensity of people to join a protest, and it measures the fraction of other people that need to be already involved for someone to decide in favor of joining as well. It can be measured on a global level, as when we take into account how many protesters are already in the streets; or it can be measured on a local level, that is, as when we count the number of activated people in our circles of friends and relatives. Networks define the smaller group of reference to which people pay attention. Compared to Olson's approach, thresholds introduce more heterogeneity in the population of rational actors: some will have low thresholds (they will be first-movers or leaders), whereas others will have high thresholds (and will tend to be followers).

Threshold models try to understand how the diversity of intrinsic inclinations to participate in a collective effort impact on aggregated outcomes (Watts and Dodds, 2010). The ultimate number of people mobilized actually depends on how thresholds distribute in the population. It also depends on how networks mediate the process: two actors with the same propensity to participate might join at different times if one is connected to a larger number of people or if the group of reference behaves differently. Attaining a critical mass on the collective level depends on being able to activate a sufficiently large number of low threshold actors that are also well connected in the overall network structure. Again, this approach to collective action adds important nuances to the picture drawn by Olson's classic approach: individuals' self-interest and the incentives designed to lure them into collective action are not enough to understand the emergence of protests; networks of interaction, and how they allow information and behavior to diffuse, are also important elements of this collective dynamic.

The mediating effect of networks is particularly relevant in this era of new media and digital technologies, when connections and interdependence are more prevalent than ever. Research on these network effects is also becoming easier to conduct: digital technologies give protesters better tools to organize their actions; but they are also providing researchers with better data to analyze more accurately how episodes of collective action emerge.

The Digital Approach to Collective Action

Most approaches to digitally enabled collective action can be summarized with the idea of "organizing without organizations" (Shirky, 2008). However, as threshold models have long tried to highlight, this form of self-organization has been observed in many empirical settings that precede the existence of new media. Massive protests can emerge in the absence of formal, hierarchical structures as long as there are networks of communication that facilitate the diffusion of information and behavior. Social networks have long channeled that sort of dynamic (Gould, 1991; Lohmann, 1994). What is intrinsic to new media is the speed and scale at which diffusion can happen. Online networks and mobile technologies make exposure to information constant; this means that the spontaneous emergence of protests takes significantly less time, making it easier to attract the attention of a larger number of people.

However, technologies never determine the outcomes of what are essentially human dynamics: that online networks can spread information more efficiently does not necessarily mean that they are always efficient. In fact, for every instance of successful massive mobilization, there are many examples that fail to take off. It all depends, in the end, on how technology is used and how its affordances are exploited (Earl and Kimport, 2011). Likewise, explaining the use of digital technologies is different from explaining the determinants of protest behavior – values, attitudes, political efficacy, and motivations are still the key theoretical elements that explain mass political mobilization (Opp, 2009; Anduiza et al., 2012). Finally, digital technologies do not necessarily challenge the logic of collective action: online petitions, for instance, can now accumulate a critical mass more quickly, but the mechanisms underpinning its success have not changed (Earl and Kimport, 2011). Only certain forms of protest make use of technological affordances that were not available before, like DoS attacks; these are the empirical instances of collective action that might require rethinking classic theories.

Olson's logic was built on the premise that the provision of a collective good requires interactions in small groups: this facilitates coercion and the application of selective incentives. However, digital technologies are reducing organizational costs and allowing new forms of incentive and norm creation in large groups. They are also blurring the boundary between the private and public domains: networks that are personal and not necessarily political in nature can now be swiftly mobilized for

political purposes (Bimber et al., 2005; Lupia and Sin, 2003). Many examples of digitally enabled protests (from the anti-globalization movement in the 1990s to the wave of political protests that started in early 2011) challenge the explanatory capacity of classic approaches to collective action – and they highlight the importance that networks have as the main structures of communication.

The Evolution of Digitally-Enabled Protests

Protests enabled by digital technologies can be differentiated in two stages: a first stage of Web-based activism, and a second stage of social media activism (González-Bailón, 2013). In addition to being chronological, what differentiates these stages is the nature of the technologies employed (or the affordances of the media) and the prevalence of those technologies among the general population, not just among those politically inclined. Early empirical examples that belong to the first stage include the 1994 Zapatista movement (indigenous protests that were projected globally from the remote territory of Chiapas in Southern Mexico); the 1999 Battle of Seattle (the first big mass demonstration that used Internet technologies to coordinate protesters against global financial institutions); or the international campaign to ban land mines (a coalition on nongovernmental organizations (NGO) that won the Nobel peace prize in 1997, having used online technologies to raise awareness and gain prominence). More recent examples, which make digital protests transition into the second stage, include online platforms like 38 Degrees and MoveOn (which help bring people together to coordinate protests and organize campaigns); the Anonymous group (who use hacktivism as a way of protest); and, most visibly, the protests that erupted around the world in 2011, including the Occupy Campaign.

What characterizes the first stage of digital protests is the emergence of transnational networks, or what some have called a 'global civil society.' This was made possible by the increasing availability of Internet and Web technologies. The Zapatista movement stands as one of the most prominent examples of these early stages: this movement illustrates how local struggles could grab the attention of an international public by leveling their digital presence. Organizations (NGOs and advocacy groups, mostly) were the crucial nodes in these transnational networks, and Web sites and electronic mailing lists offered the main dissemination tools. As Internet technologies evolved, those transnational networks matured and a global public domain started to consolidate: the Web carried information to which everybody (with the appropriate search) could be exposed, and this created a common ground that acted as a global soundboard.

The second stage of digital activism brought a significant change: it made transnational networks easy to reach for individuals. Citizens could now bypass organizations and harness the power of communication networks more easily, with the ability to exploit the domino effect of their connections without the support of powerful organizations orchestrating the action. In other words, common users became the crucial nodes in the network. Social media and mobile applications blurred the (up to then) well-defined distinction between private and public connections, a division that still shaped the first generation of Web technologies.

The First Wave of Digital Protests

During the first wave of digital protests, the Web was the main weapon. Organizations were instrumental in the dissemination of information, and online networks, in the form of Web sites and hyperlinks, created the communities delivering that information and disseminating calls for action. Research on the Web presence of the Zapatista movement relates their online centrality to connections with the Web sites of hundreds of global NGOs that offered an international network of solidarity (Garrido and Halavais, 2003): all these organizations opened the routes through which attention and support could travel to the Zapatistas' cause. Given the importance of hyperlinks to direct traffic (either directly by means of clicks, or indirectly by means of search algorithms) being central on the Web was crucial to gain public attention.

During this stage, the Web acted as an amplifier of protest messages: it facilitated the formation of links across causes that until then were scattered in off-line collaboration networks, forged by NGOs and advocacy groups but often invisible to the public. Web presence was not a sufficient condition for immediate success (for every local struggle projected to global visibility, the Web sank many more into oblivion, Bob, 2005) but it offered a springboard to which very few protest movements would have had access before.

In addition to the dissemination of information, the Web also offered the infrastructure to launch new actors to prominence. Particularly relevant among these are independent media sites like Indymedia. This platform gave visibility to a global network of journalists that stood as an alternative to corporate media. It was instrumental in the coverage and coordination of antiglobalization (or global justice) protests, starting in Seattle in 1999, during the World Trade Organization conference (Shepard and Hayduk, 2002). Protesters could use these online resources to coordinate their actions, but also to build their own story of the events, on the margins of traditional media narratives and supported by their own graphic documentation, digital and easy to publish online.

These Web networks were very powerful in reaching audiences and creating awareness. The International Campaign to Ban Landmines, awarded the Nobel Peace Prize in 1997, is often cited as an example of how the Internet increased the speed and efficiency of group mobilization: in this case, to coordinate the efforts of six founding NGOs to build a global network in dozens of countries for the elimination of anti-personnel land mines. Five years after being launched, the campaign attained an international treaty.

Online petitions are an important component of how the Web transformed political protests. Because of the increased connectivity, and the lowering costs of information diffusion (no need of paper, print, or stamps), the number of supporters and signatories could be scaled up in shorter time frames. Posting on a Web site the details of a petition, and encouraging subscription to electronic mailing lists facilitated the diffusion of calls. Research on the spreading dynamics of a petition to organize opposition to the war in Iraq in 2002 shows that the chain letter unfolded in a narrow but very deep treelike

pattern: it did not reach many people in a few steps but through many steps that reached a few people at a time (Liben-Nowell and Kleinberg, 2008). E-mail lists allowed, in other words, successful instances of large-scale diffusion which before would have been more difficult to attain or would have been more easily broken at any of the stages they need to unfold.

In all these instances, the Web created global circuits of information and some shortcuts to reach potentially wide audiences. But people, the audience, had to enter those circuits to be exposed to the information. As content producers, users also had to create their networks from scratch: publishing a Web site did nothing to raise the profile of a cause if no other Web sites linked back to it, granting visibility in an otherwise vast and unchartered sea of information. The ability to mobilize resources, in the form of solidarity networks, was still an issue for most organizations wanting to raise awareness – and the reason why successful instances of mobilization were more often than not an exception.

The Second Wave of Digital Protests

During the second stage of digital protests, social media arrived to highlight the power of personal connections. The evolution of Web technologies, and the growing number of Internet users, changed some of the mechanisms by which online networks help protests emerge. The Web ceased being about creating new networks; new applications started to emerge that capitalized on already existing social networks. Social media and networking sites (like Facebook or Twitter) make personal networks the backbone of their services, and the main channels for information diffusion. In this new information environment, users do not need to enter an online circuit to be exposed to specific types of information (as they had during the first stage of online technologies); now it is their contacts and groups of reference (formed by colleagues, friends, and relatives, but also acquaintances and public figures) who bring that information without request.

During the first stage of digital protests, people had to search for calls for action; now, these calls come via friends, or friends of friends, in the constant flow of information that defines social media. This change has a significant impact on information diffusion: we are more likely to pass on information if the source belongs to our social circles (Bakshy et al., 2012). Social media allow us to monitor those circles of friends and acquaintances with constancy difficult to replicate off-line. This is crucial to understand the way in which protest movements emerge today; but two other transformations are equally relevant: mobile connectivity, and the infiltration of mainstream media into personal networks.

Mobile connectivity allows people to be constantly exposed to streams of information, regardless of location. This accelerates their reaction times to calls for action. It also means that the technology is more flexible to organize and coordinate protests once they are in motion, especially if they involve the management of camps in public squares, as it happened in 2011 in Cairo, but also in Madrid or New York (Castells, 2012; Gerbaudo, 2012). The integration of mainstream media and professional journalists into personal networks is also important: it means that online networks are not as clear an alternative now to corporate media as they used to be during the first wave of digital activism. Users now do not write on the margins of mainstream media to provide alternative views (as it happened with platforms like Indymedia); instead they engage in direct information exchange with mainstream media. Twitter is the most prominent example of this two-way mode of communication across old and new actors.

The consequence of all these shifts is that the boundaries of the private and public spheres – as predicted by early criticisms of the classic logic of collective action (Bimber et al., 2005) – get fuzzy: the channels of communication for private and public talk are conflated into the same networks; that is, a significant portion of information shared online goes through networks that are not necessarily political, but that can be activated for political purposes as circumstances arise. The activation of preexisting networks for a political cause is more effective than having to unfold (or revive) ad hoc communication structures: it replicates recruitment dynamics through social networks with the same logic applied prior to the emergence of the Internet. The key is that it is more effective to have a friend telling you of a petition, or of the date and venue for the next protest demonstration, than an impersonal organization to which you might not even belong.

The composition and rhythm of online protest networks change in this second stage, but many of the characteristics that were already highlighted in the early Web manifestations remain: online networks are still decentralized structures that pull together local sources of information and create efficient channels for a (potentially global) diffusion. However, support networks built with Web sites and hyperlinks responded to strategic planning by organizations; personal networks in social media sites, on the other hand, emerge spontaneously out of individual choices: some users are better connected than others, and some have geographically more diverse networks, creating the bridges that might lead to global diffusion dynamics.

The wave of protests that emerged in 2011 (from the Arab Spring, to the Spanish 'Indignados,' or the Global Occupy Campaign) seems to reflect this global interdependence of localized, personal networks. However, systematic research in this area, uncovering the actual bridges and network mechanisms that facilitated diffusion across national borders, is still lacking. Also, this wave of protests cannot be understood without taking into account the pervasive role of mainstream media: in spite of being part of many of those online networks, mainstream media still have a gripping influence in the spread and framing of news from the top-down. Finally, protest movements are not caused by social media activity; social media offer just a vehicle (one of the many) to help a protest movement rise from the shadows; the crucial explanatory factors are still social and economic, if not historical. But as a vehicle, it is true that online networks offer avenues for protest mobilization that allow unprecedented reach and speed. The following section explains why.

Online Networks and Protest Diffusion

The success of protest mobilization through online networks is difficult to predict because it depends on the right alignment of

conditions on different levels: at the level of local interactions (where personal information contexts are shaped), and at the level of global activity (where diffusion branches collide). Much in the same way as chain letter trees exhibit a narrow and deep structure, requiring many nested layers of forwarding to reach a large number of people, so the chain reactions in protest networks follow intricate paths that are difficult to anticipate – among other things, because they might end or split at any stage.

Diffusion chains to join a protest might end because people stop forwarding the information through their personal networks; and so information ends up being trapped in their social circles. The reasons why people might not want to continue a protest chain vary: maybe they did not register enough activity in their local network to consider the protest relevant (and were averse to the idea of becoming one of the leaders); or they were against the protest and decided not to join, in spite of local pressure; they might also break the chain for a number of reasons that are independent of the protests: social media, after all, operates in a world that still constraints online activity and puts a limit to political engagement.

The sum of all those individual decisions is also not enough to anticipate the emergence of large protest events. The cumulative effects of individual behavior are not linear: as Section The Importance of Interdependent Decisions explained, networks activate feedback mechanisms that can propitiate a sudden change in the mobilization dynamics, like exponential growth in the number of protesters recruited. These mechanisms are at the heart of network complexity – and the unpredictability of their dynamics – but they can be dissected and reconstructed to uncover their logic.

An analysis of the protests that emerged in Spain in 2011 (the 'indignados' or 'outraged' movement) does precisely this: it reverse engineers the network mechanisms that helped the protests grow from nowhere (González-Bailón et al., 2011). It shows that recruitment initiatives started all over the network (i.e., at the center and at the periphery) but that information cascades were more easily triggered by users who were sending protest messages from the core. A follow-up study, though, showed that a few influential actors – common users before the protests – were catapulted to global network prominence in a matter of days (González-Bailón et al., 2013), which testifies in favor of social media as a tool to build visibility when there was none.

Most chain reactions in online networks burn before long, that is, before they roll over to reach a large number of people (Borge-Holthoefer et al., 2013). And whereas large cascades tend to start at the core of the network, network centrality is not a guarantee of success. Interdependence makes chain reactions more likely, but also more unpredictable and rare. What has changed with social media is that there are more attempts to trigger those reactions – often without the large-scale vision or motivation; more attempts means that there are more successful cases, as the buzz around viral content attests. And political content is effervescent by nature, which helps create the rush that accelerates cascading behavior. But there is nothing intrinsic in online networks guaranteeing the success of digital protests.

Future Lines of Research

The protest movements that have emerged in the last two decades provide evidence that Internet technologies are helping users bypass traditional modes of mobilization. But answering why and how new media facilitate self-organization and information diffusion requires a careful approach to the networks they help forge, and to both the successes and the (more abundant) failures. The Web and social media have altered the way in which people interact and come together, making formal organizations less necessary and audiences potentially wider; but at the core of the process there are still motivations and chains of influence that transcend the technical capabilities of those tools: the main action still depends on people's willingness to act.

The study of online networks is still in its infancy, and the implications for the study of protest mobilizations in the digital age are yet to be fully understood. But social media have provided – in addition to tools for protesters – valuable data that are helping researchers gain insights into how people come together, and how networks facilitate or hinder the emergence of protests. Research to date has pointed to three relevant dimensions: the dynamics of message propagation and recruitment; the geographical spread of social networks; and the scales of human mobility. All three aspects are relevant to understand why some attempts to organize protest mobilizations succeed, and most fail. Future work will have to shed more light on these, especially if protest organizations (or governments or NGOs) are to draw lessons to exploit the potential of new media.

The available evidence suggests that collective action is more transient now, and that spikes of attention and protest bursts do not easily crystallize into more stable trends or outcomes. Protests can never become, by definition, stable and fixed organizational structures – their power lies, precisely, in their exceptionality. Online networks have proved to be good at channeling that sort of fluid commitment. However, as Internet and Web technologies continue to mutate, so will the strategies that are used to irrupt the political scene. In this, technology is only one part of the story, a very volatile part: soon, Twitter accounts will look as outdated as the gadgets the Zapatistas used in the Chiapas jungle to project their message. An accurate picture of how digital technologies are changing protest movements has to focus less on the nature of the technologies and more on how they are used to join people together in a collective effort. This article has introduced the main concepts that can help develop that theoretical understanding.

Social Protest Movements and Social Work Practice

Abstract

The study of social protest movements is well established in the sociological literature, but its influence on social work's more progressive practice has been less well documented and discussed. That is until the reemergence of a capitalist recession across Western democracies in the late twentieth century, which resulted in massive rises in unemployment, homelessness and other social manifestations of poverty, and structural and personal disadvantage, characteristic of postwar Europe. Recalling the activism of social workers during the 1970s and their links with the radical milieu of the time, many social work scholars are calling for a reengagement with contemporary social protest movements to speak out against the unchecked growth in inequality and social disadvantage that has resulted from the recession and compounded by the more recent global financial crisis. This article explores what a more serious engagement with the politics of social protest movements might have on social work's more progressive politics and practice, especially the more change-orientated focus of community work and its links with social action.

Introduction

The explosion of mass social protest movements in the 1960s, 1970s, and 1980s across Western democracies resulted in the study of this phenomena going forward at an unprecedented pace as these protests gave rise to new ways of thinking about and engaging in the world (Della Porta, 2008; Tilly, 2012). Although protest movements were not new, what was new was their breadth, depth, scope, visibility, and their global reach. The women's movement, the civil rights movement, the peace and environmental movements, trade union and labor movements, gay and lesbian and human and animal rights movements, cultural and indigenous land rights movements, prodemocracy and anticorporation movements became formidable forces for social change in the second half of the twentieth century reawakening the potential strength of political protests and consequentially giving new potency to social unrest as a mean of challenging the status quo (Della Porta and Diani, 2009; Tilly, 2012). Issues concerning gender, ethnicity and race, sexuality, ability, democracy, human rights, and social justice were to be considered in the creation of more egalitarian social relations between and among different populations (Dominelli, 2006). Radical social work of the 1970s shared many of the aims, philosophy, and social action strategies characteristic of these social protest movements (Bailey and Brake, 1975; Langan and Lee, 1989). The social worker as agitator was an important aspect of radical practice.

Activists who were fed up with their sense of alienation and the social, political, economic, and cultural oppression and human rights abuses in their countries went out into the streets to give notice to whoever was listening (sometimes peacefully, sometimes violently) that these repressions would no longer be tolerated. Fighting for their universal entitlement to democratic governance and political openness, as well as basic human and environmental rights, social justice outcomes in legal, policy, and planning processes alongside their innate right to safety in expressing differences, to seeking equal educational opportunities and rights to a productive life, these protesters signaled that these rights would be fought for with sustained resilience (Della Porta and Diani, 2009; Tilly, 2012). The more recent protests across the Middle East (also known as the Arab Spring), the M-15 movement in Spain and the United States (US) inspired Occupy Wall Street movement, which swept the world in 2011–12 as well as smaller uprisings in sub-Saharan Africa, the Maldives, the Solomon Islands, and the democratic movement in Africa makes the study of this phenomena a current issue. Especially for social workers concerned with fighting for social justice, democracy, equality, and freedom from oppression in a world where poverty, injustice, intolerance, discrimination, and violence seem to be escalating across the globe (Dominelli, 2008, 2012b; Lavalette, 2011; Beinin and Vairel, 2011).

This surge in social movement activity has also helped rearticulate a more radical social work 'Left' agenda and the importance of social work in taking a stance, once again, against the exploitative regimes of the capitalist class and its neoliberal economic order and the inequality and injustice it brings to large sections of the population (Gray and Webb, 2013). Challenging social injustice is to challenge the political construction of the oppressed and marginalized as defined by the state and the power elites. Linking social movements with the radical reawakening of a progressive politics in social work; a politics that regards social problems and human suffering as having its root cause in the large-scale social and political processes rather than as a consequence of individual pathology or deficiencies, is timely given the growing inequality between people, communities, and countries. Linking with contemporary social protest movements will ensure citizen service users are treated equally in the allocation of resources and the benefits of the society more generally in order to create new, nonoppressive social and political relations (Dominelli, 2002b, 2008; Ferguson and Woodward, 2009).

While questions about what motivates and unites people to form resistance against seemingly powerful adversaries such as the state or military–industrial complexes are still being explored what is certain it that social movement protests remain, more than ever, people's choice for mass resistance

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28085-9

when abuses in power pose threats to 'ordinary' peoples' day-to-day access to material needs and resources as well as their social, political, and cultural rights despite the very real repressive counteraction they face (Della Porta, 2006; Snow and Soule, 2007). They represented the collective voice of disaffected individuals acting defensively and offensively for themselves by demanding protective legislation for their rights and real, material solutions to fix the wrongs being perpetuated against them (Crossley, 2002; Thompson, 2010; Buechler, 2011). Highly visible, articulate, and self-confident these activists, working outside of and against the state and its interests have developed a low cost, relatively effective, decentralized method to challenge a centralized, extraordinarily well-organized, seemingly impenetrable, and well-defended adversary (Snow and Soule, 2007; Sklar and Dublin, 2011).

So what is it about social protest movements that has and continues to capture citizen action? And what role has social work played in response to these movements' activism. First, I will discuss social movements in general then I will turn my attention to social work's response to this phenomenon.

Social Movements

Social protest movements have been variously defined as the new politics of international action (Cohen and Kennedy, 2000), as organized efforts by significant numbers of people to promote social change (Crossley, 2002), in Marxian terms as signs of impending collapse of the existing capitalist order or in postindustrial terms as attempts by individuals to move concerns away from class politics to apprehensions with their own sense of belonging, self expression, cultural, and individual freedoms influenced by the lifestyle politics of the hippie counterculture of the time (Pakulski, 1991). Influentially Touraine (1988, 2007) describes social movements as conflicts about the social control of cultural patterns and expressions rather than (just) material interests or class politics. He does not deny the importance of class politics as a site for movement activism but regards the fight over the main cultural patterns of the society as *the* primary site for struggle and social challenge. The aim of this struggle, he argues, is to gain control over the compromises of the past settlements that determined class, gender, race and culture, and ethnic and sexual arrangements in order to generate new meanings in these settlements. Beck (1997) talks about antipolitical politics or mass protests, where disaffected individuals confront injustice and impersonal repressive power with the only thing at their disposal – their own humanity and Leonard (1997) regards new social movement activism as framing a politics of hope for the politics of the future. Feminists in making their personal experience of oppression a public issue contributed to the social transformation of all women, not just their own lives and demonstrated how social action can be informed by personal issues to influence social change (Langan and Day, 1992; Dominelli, 2002b, 2006).

Crossley (2002) demonstrates how social movement protests have always accompanied unpopular or exploitative acts of social, cultural, and political expansion especially if these expansions rendered significant groups of people powerless, or uprooted the original inhabitants from their lands or cultures and deprived them of fair and equitable access to their country's resources and riches. For example, the religious, trade and capital, and cultural movements that sought (and fought) for global dominance during the sixteenth, seventeenth, and eighteenth centuries encountered strong resistance from the original inhabitants. In broader terms, antiimperialist, anticolonial movements, international trade union solidarity, and international workers movements date back to late nineteenth century and cultural internationalism (the protest movement challenging the dominance of Western ideas about economics, culture, and intellectual traditions), the women's suffrage and more organized global antislavery movements also assumed greater significance after World War I (Crossley, 2002; Snow and Soule, 2007; Smith, 2008). Indigenous struggles to protect their land, culture, and language were always an important part of these resistances from early settlement days. Indigenous resistance such as the mass slave revolt in Haiti and the sustained resistance by indigenous peoples in North and South America, Australia, and Pacifica are examples of this resistance (Guadalupe Vargas Hernandez, 2005; Merlan, 2005).

Social Movements and Social Work Practice

Powell (2001) noted as do others (Dominelli, 2002a, 2012b; Ferguson and Woodward, 2009; Allan et al., 2009; Mullaly, 2010) that social work has always been influenced by the politics of the day, sometimes more conservatively such as the Charity Organisation Society while at other times more progressively such as the Settlement Movement in the UK, which influenced the more community-focused early social work development in the US in the late nineteenth century. In more contemporary times, social workers have worked alongside activists in bringing attention to the pressing social, cultural, and political concerns they encounter in their everyday work as frontline practitioners and social policy activists (Noble, 2007). We know from personal experience that many social workers were out in the streets politicking alongside their clients, other professionals, and student activists. Joining with the new wave of collective consciousness that gripped the global world social workers stood in solidarity with these protesters and experienced a new found power in the 'collective' and its use as an immediate and effective strategy to demonstrate against, now publicly 'named,' long-standing grievances against the state, global companies, and interests as well as other forms of authority and repressive power. Fighting against all forms of oppression including lifestyle choice and ability as well as against the inequality in income and wages, access to money, and the benefits it brings and other forms of institutional domination and oppression, social workers used social action to fight for their own sense of justice as well as for the service users in their care (Thompson, 2010; Dominelli, 2012a,b). Social workers and community workers also participated in the United Nations initiatives such as the Copenhagen Social Development Summit and the Beijing Action Platform for Women in 1995 and were very active in the formulation of the Millennium Developmental Goals in 2000 (Dominelli,

2006). As stated above, what is new about these more contemporary protests is the vastness of their reach, the impact of their actions and the success of their demands or the degree with which they can unsettle the status quo.

Social work's attention anti-oppressive practice (AOP) has quite a body of seminal texts to its name. In particular, Ferguson and Woodward (2009) Dominelli (2002a, 2006, 2008, 2012b), Baines (2007), Allan et al. (2009), and Mullaly (2010) give a comprehensive overview of social works more radical theory and practice and these authors continue to be strong advocates for social workers to be active in naming and then fighting for social, political, cultural, and more latterly environmental justice. This progressive practice links back to the early radical social works' explicit class analysis and its links with the trade union movement, which influenced many social workers to form collectives against the state and to critique the nature of work and capitalist production and its role in reinforcing unequal social and political relations (Bailey and Brake, 1975; Langan and Lee, 1989). Following a class analysis, feminist social work confronted the gendered nature of the social, political, and cultural order demanding women free themselves from male power and its pervasive dominance in oppressing women and children. Feminist campaigns from abortion issues, to reproductive rights and decriminalizing prostitution, eliminating domestic violence, and securing better health initiatives showed how practice can result in policy and service provisions to change women's lives for the better and is well documented in the literature (Langan and Day, 1992; Dominelli, 2002b, 2006). AOP extended an analysis of class and gender to include a critique of ethnicity, sexuality, ability and power, and social relations not in distant or abstract terms but as material conditions that reproduce social, political, and economic inequalities in individuals' lives (Baines, 2007; Allan et al., 2009). This progressive practice challenged the oppressive social arrangements that excluded people from accessing resources or participating in public policy debates and political decisions that affect their lives. Attention was drawn to incidents of mass human rights violations, abuses in political power, mass misappropriation of wealth and natural resources, widespread corruption, economic decline and subsequent rise in levels of unemployment and poverty, ethnic conflict, religious repression and gender violence in their communities, and beyond in order to bring about more socially just relations and outcomes (Noble, 2004, 2007). Sociological literature, especially, critical theory became a feature of social work discourse and scholarship replacing the emphasis on psychological and individual well-being. Linking with critical theory, a progressive social work argues that structural inequality and individual oppression are a result of the dominant sociopolitical, cultural, and economic arrangements (or settlements) not the result of individuals who receive the consequences of these defective arrangements (Leonard, 1997; Pease and Fook, 1999; Allan et al., 2009).

These political ideals shared the ideals of social protest movements fighting for and defending citizen's rights, including the right to work, to adequate income, to education, to health, to a healthy environment, and to the protection of all citizens' right to engage in political, social, and cultural life. In applying these ideals to practice social workers were encouraged to highlight the social and human consequences of violence, suicide, high rates of incarceration, mental and physical ill health, poverty, social, religious and cultural marginalization and political repression, trafficking of women and children, environmental degradation, the mass atrocities against indigenous peoples and the impact that torture and war has on individuals, their families, and communities (Annetts et al., 2009; Motta and Nilsen, 2011). Importantly feminists argued for social workers to make the political personal in their own lives. Many social workers took up this challenge, as cited above in securing the presence of a social justice, human rights agenda for women and children as well as for people with disabilities, people receiving psychiatric care, people with learning difficulties, children in care and survivors of abuse and family violence, older people, asylum seekers and people living with HIV/AIDS, and other users in social support and income maintenance services (Noble, 2007; Ife, 2010). The social worker as agitator also helped establish governmental inquiries into the abuses children, the differentially abled, Indigenous peoples, and asylum seekers experienced under the care of the state as well as breaking down the walls of mental health institutions. Currently social workers are continuing their activism against the new austerity measures of neoliberal philosophy, which has a strangle hold on most Western counties, post-Global Facial Crisis, and the environmental movements in protecting the world's natural resources against the rampant depletion by unchecked consumer consumption (Ferguson and Woodward, 2009; Lavalette, 2011) Dominelli (2012b) in promoting green social work extends social work activity into the realm of social ecology and environmental and cultural sustainability.

The 'Dark Age' – the Impact of Neoliberalism on Social Work

As we review this history with the wisdom of the present situation it must be acknowledged that despite the enthusiasm for change toward a more active politics, an engagement with service users for fairer access to service and resources and attempts to increase their political power, social works attempt to change policies toward a more social justice focus has been patchy at best and ineffectual at worst (Powell, 2001). The salient fact remains that even the more progressive form of social work needs government funds and policy support for its well-intentioned ideals. Governments are reluctant to finance radical politics, especially organizations seeking political upheaval or are critical of their policies and practices. Dominelli (2012a), Ferguson and Lavalette (2011), Mullaly (2010), and Noble (2007) in particular document how the mood and enthusiasm of the radical ideals of the early 1970s and 1980s was gradually extinguished by the pervasive influence of neoliberal philosophies. Its not that the radical scholarship was not evident (see Dominelli, 2002b, 2008) or that there were no more attempts at social change; it is just that the overall impact of neoliberalism placed its scholarship and activities in its shadow, especially since the late 1980s. Many

contemporary scholars have summarized the impact of the neoliberal agenda on the welfare system and services as having resulted in: the primacy of individual enterprises over state-funded services, of private-based services over publicly funded ones; self-motivational ideals over collective aspirations to care for the 'common good' and finally small government and reduced welfare services and provisions over a progressive welfare state and universal welfare provisions undermining the traditions of working-class politics and social democratic considerations (Powell, 2001; Ferguson and Woodward, 2009; Ferguson and Lavalette, 2011; Dominelli, 2012a). The dismantling of the welfare state and its welfare provisions was/is in progress in favor of the liberal/conservative manta of individual pursuits over the collective and economic austerity over social capital spending and infrastructure developments.

The dismantling of the welfare state is exacerbated, argue Ferguson and Woodward (2009), by the pervasiveness of case management as the new practice model, which "undermines the worker-client relationship, transforming it into a financial relationship, with the client as the reconstructed consumer" (p. 148.). Even in the voluntary sector, case management is the proffered model of care despite, for example, New Labor's attempt in the UK to strengthen civil society through encouraging active citizenship and addressing social exclusion by growing and resourcing the voluntary, community, faith-based and private networks, and organizations separate from the state (Ferguson and Woodward, 2009). The role of the social worker as a change agent is almost invisible, leaving the social control aspect intact. There is no denying the contradiction and resulting tension between individual and social change and the social control aspect of social work's state-based role that has plagued social work since its inception. So where to now?

As social work's main concern is to work with people, families, and communities that experience oppressive social arrangements. Oppressive arrangements result from the effects of long-term economic readjustments and the movement of capital and manufacturing offshore and under and unemployment of large sections of the community and the effects of systemic and personal violence, of poverty, and homelessness as well as under representation in politics, financial and governing institutions, the classroom and universities. The call for social work to reengage and reconnect with social movement protest and social work's more progressive politics especially evident in social action and community work still seems relevant and for this reason timely to revisit.

Social Justice, Human Rights, and Progressive Politics

Despite the hostile sociopolitical climate for progressive ideals and sentiments and the pervasiveness of the neoliberal philosophy, progressive social work practice, and its commitment to emancipatory ideals, although lacking visibility in practice, is still evident in its scholarship, mission, philosophy, and theory even if some of its shine and potency has been lost (Rogowski, 2010). Indeed an ongoing commitment to social justice, human rights, and progressive politics is increasingly evident in many of the current social work literature and in some cases has been strengthened, especially in the scholarship coming from scholars in Australia, Canada, and the UK (Pease and Fook, 1999; Powell, 2001; Allan et al., 2009; Dominelli, 2002a, 2012a,b; Mullaly, 2010). Despite the neoliberal agenda, a progressive form of social work can also be found in social work curricula across international programs. For example, social work programs in the US, UK, Aotearoa New Zealand, South Africa, Canada, People's Republic of China, Hong Kong, Vietnam, and Cambodia's (just to mention a few) demand (with varying emphasis) a commitment to social justice, human rights, and for theories of ethnicity, race and whiteness, diversity, racism, and power to be taught in conjunction with practice skills in their curricula (Noble et al., 2009). This is also explicitly evident when new and developing programs use the International Association of Schools of Social Work's (IASSW) global standards (http://www.iassw-aiets.org/global-standards-for-social-work-education-and-training) as a guide when designing their programs and the international definition of social work informs many of these program's philosophical underpinnings. This quote from the definition that social work

> promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilising theories of human behaviour and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work.
>
> http://www.iassw-aiets.org/international-definition-of-social-work

reminds us and keeps alive its more progressive commitment to social change and social justice.

An important development in reasserting social works philosophical commitment to social justice and social change is its own global movement beginning in 2008 when the three partner organizations – IASSW, International Council on Social Welfare, and the International Federation of Social Workers – led by their respective presidents came together to consider specific actions to address rising inequality and its challenges. The Global Agenda, as it is known, has an explicit aim to work as a collective across its constituent members and communities to influence the UN's forthcoming initiatives, in particular, the post-2015 development agenda as well as to work with groups and communities worldwide to promote social work's role to protect and promote social justice, human rights, and sustainable development as central to its emancipatory mission. A policy document will be produced for the Tripartite conference in Melbourne in 2014 following extensive consultation across the global social work community (http://www.globalsocialagenda.org). This initiative reaffirms social work as a profession working in the human services and supporting people to achieve the best possible levels of social and personal well-being and working tirelessly to achieve human rights and social justice through social development, social and systemic change,

advocacy, and the ethical conduct of research. The Global Agenda is a collective effort by all social workers to repoliticize social work and recapture the radical manifesto of the 1970s and 1980s and the subsequent social protest and agitation it engendered (Bailey and Brake, 1975; Allan et al., 2009; Ferguson and Lavalette, 2011; Dominelli, 2012b).

Lavalette (2011), Dominelli (2002b, 2008, 2012a), and Allan et al. (2009) call to critical practice or social activism are relevant here. They argue that if social work takes its commitment to social justice and human rights seriously then, for the sake of the profession and the service users, it needs to articulate another way of doing business than what has been evident during the last decades of the neoliberal agenda. That is to demonstrate another way other than servicing a shift to the private sector, of passing the responsibility for managing risk back to the very families and communities who need such help and to challenge the increased corporatization of the whole welfare sector and return a humanity into the social work discourse that the social movement protestors are using to inform their global activism (Powell, 2001). So how can this happen?

Community Work and Social Action

Mayo (2005) argued in the 1970s that the opportunity for radical practice through community action was a missed opportunity. However, she still maintains that fostering new alliances with service users, acting collectively with broader coalitions such as social protest groups that are fighting for rights to employment, and/or adequate income, clean food and water, democratic citizenship, end of poverty, war, torture, ecological and social sustainability, and other socially progressive ideals "will always reflect a powerful alliance for resistance" (Lavalette, 2011: p. 127) and a force, I would add that progressive social work should once again harness. Mullaly (2010) and Ife (2010) argue that social workers have an ongoing responsibility to educate themselves and others about the consequence of imbalances in power, resources, decision-making, and quality of life brought about by the neoliberal and globalizing agenda and form alliances focused on resisting their impositions and social manifestations as sited in the early radical critique. The argument here is to take note of the discourse of progressive politics and the richness of its possible trajectories and its long-term links with social action and social justice that is, fight to give individuals or groups their 'due' within society. Much like the early manifestations of AOP, social workers need once more to agitate for the equitable distribution of resources, access to public benefits and services, equality before the law, and social and environmental development. This can be achieved, argues (Mullaly, 2010), through advocacy (personal and political), consciousness raising, and active promotion of fair distribution of resources and social change toward human betterment irrespective of group membership or social positioning and provides the most obvious platform for action (Noble, 2007). Concerned with advocacy and empowerment community action aims to address and change the oppressive social arrangements that exclude people without power from accessing resources or participating in effective decision-making that relate to their lives so that they can be active in public policy debates and political decisions (Baines, 2007; Mullaly, 2010). It assumes both an individual and group willingness to redress and refigure power imbalances informed by a social justice agenda. Through self-reflection and collective action, individuals are encouraged to identify and name the ways in which social structures shaped their experience of disadvantage and the way that orthodox social work was complicit in the process (Noble, 2007). Weeks et al. (2003) provide a beginning framework for global community action for those social workers looking for a way of resisting the changes associated with the new economy and current economic globalizing activities. They argue that linking local issues to global and regional analyses; working with international human rights instruments; developing transnational civil society, regional networks, and coalitions for advocacy and action by maximizing cyberspace; and developing alternatives to globalization would give progressive practice a 'heads up' and connect their praxis clearly within the social protest movements discourse (Weeks et al., 2003: pp. 13–14). These community workers are also keen to see a reimaging of local communities and action toward democratization of local economic relations, a move in line with social ecology and sustainability activism (Mullaly, 2010; Dominelli, 2012b). Tesoriero (2010) and Dominelli (2012b) see social work's community action groups' involvement with the global justice movement, and the antiglobalization, the ecological and sustainability movements and their links with social justice and human rights strategies as representing a vision of a future society achievable through repolitization of social work practice and its links with social protest movements. Ferguson and Woodward (2009) argue for social workers to relink with the current service users movements (namely mental health, disability, and indigenous resistances to welfare interference) to further the ideals of social work in the public arena. It is social protest movements and their capacity to generate significant social change in a way that no longer seems possible for more conventional politics or for that matter the more conventional casework and case management approach that can help renew and refresh social works value base and inspire a new outrage at past and present injustices. In responding to long-standing government and other policy-making institutional grievances, social protest movements have the capacity to introduce new political actors into contemporary politics whose sole purpose is to alter the status quo as a way of resolving their grievances and creating an alternative political climate in its wake (Tilly, 2012). The vision of these movements, in particular, can provide both a source of inspiration and as a framework for interpreting and seeking change in a planned way rather than as a purely reactive and unorganized response. It is here that Bailey and Brake's (1975) seminal work has reactivated an earlier progressive politics based in a reinvigorated community action/social advocacy approach to practice as evident in the call for a new politics of the Left by Gray and Webb (2013) and Lavalette (2011).

Community action/social advocacy social work assumes that all people have the ability to name and confront their experiences of discrimination and oppression and with collective action work toward creating a system more reflective of their true needs and ideals. Through self-reflection and collective action, individuals are encouraged to identify and name the ways in which social structures shaped their experience of disadvantage and the way orthodox social work was complicit in the process. Community action provides a vehicle for service users to develop their collective voices to express and determine social arrangements that would meet their true needs and ideals (Weeks et al., 2003; Noble, 2007). That is, community work combined with social action strategies is an ongoing and complex process of dialogue, exchange, consciousness raising, and critical reflection, education, and targeted action aimed at developing a partnership with communities to help build their own version of community that meet their needs and aspirations (Tesoriero, 2010; Weeks et al., 2003). What workers can give to the community is their passion, commitment, enthusiasm for social change combined with a vision of a better society, and a belief that change is indeed possible (Tesoriero, 2010). Activist social workers require congruence between personal values and beliefs and work practices, which frequently involve political activity outside their professional work settings. However, while social action can vary between reformist and revolutionary activist practice there can be distilled some common features. These include

1. An understanding of historical processes and the cycle of change.
2. The prioritization of the social structure in the analysis of social problems.
3. Shift from the focus on individual pathology to concentration on oppression and its many forms and sites.
4. Adoption of practice strategies that recognize and challenge the structures of oppression.
5. Development of egalitarian practices with service users.
6. The role of the social worker in activist practice (points 1–5, Healy, 2000: p. 240).
7. Use of multimedia such as art, music, literature, poetry, radio, film, drama, and social-media as means of exposing injustices and offering an alternative vision.
8. Relaying and retelling stories of successful change and current and past struggles in social work education.
9. Developing scholarship grounded in progressive politics that includes a global and local analyses.
10. Seeking creative forms of practice that link the global and the local analyses across social work knowledge, values, and skills (Dominelli, 2002b; Ife, 2010).

Conclusion

Scholarship on community work and social action and its links with social protest movements is, I argue, the most effective and salient practice method for the advancement of a more progressive social work practice. That is, a practice that will encourage the energies, commitment, and shared interests of oppressed people to work collectively to initiate the processes of change toward their liberation and freedom to expose their concerns. Let us not waste this new opportunity to harness its impact and effectiveness; let us get organized again!

Abstract

This article reviews the early history of thought linking mind and society and social psychological theories since the late nineteenth-century beginnings of the disciplines *psychology* and *sociology*. We emphasize the growth of thinking about populations in nineteenth-century nation-states, diverse theories of the early twentieth century, Lewinian field theory, growth in American social psychology after World war II, the 'crisis' of the late 1960s and early 1970s, attribution theory and social cognition, the separation of North American, European, and Asian social psychological theories, and contemporary dilemmas about embodiment and culture.

The Long Past of Theory in Social Psychology

Social psychology – like psychology *in toto* – has a long past and a short history. In the late nineteenth century, scholars began to imagine 'social psychology' as new disciplines *sociology* and *psychology* aimed for sciences of 'the mind' and 'society' respectively (Allport, 1954; Collier et al., 1991; Farr, 1996; Greenwood, 2004; Jahoda, 2007; Kruglanski and Stroebe, 2012). Carlo Cattaneo (1801–69) used the term 'social psychology' – *psicologia sociale* – in 1864. The first years of the twentieth century, several texts of 'social psychology' were published including Paolo Orano (1901), *Psicologia sociale*, and Carlos Octavio Bunge (1903), *Principios de psicologia individual y social*. But principled thought about the relationship between 'mind' and 'society' long precedes these events.

Around the *Spring and Autumn* period, Chinese spiritual leaders, notably Confucius (551–479 BCE), wrote enduring texts about the maintenance of social harmony and the ideal life. The enlightenment of Gautama Buddha (563–483 BCE) in the Himalayas initiated a spiritual tradition oriented toward enlightenment through the practice of virtue. In 'Pericles' century,' Socrates and the sophists refocused philosophy on individual morality, society, and language. Plato's (427–347 BCE) *Republic*, Aristotle's (384–322 BCE) description of the uniquely 'rational' human soul, and the theory of 'humours' originated by Hippocrates (460–370 BCE) all influenced medicine and politics in the ancient world, and the literary and scientific culture of the Abbasid Empire (750–1258). In the context of the scholastic philosophy of medieval Europe, framed by matters of Christian faith, William of Ockham (1287–1347) called for theoretical simplicity, a value that survives as 'Occam's razor.' The Italian renaissance prompted enduring reflections on 'society' as separate from such exercise of state power, such as Niccolò Machiavelli's *The Prince* (1531) and Baldassare Castiglione's *The Book of the Courtier* (1528). The former author's name also identifies a twentieth-century personality variable.

The invention of the printing press, Protestant reformations, and the Catholic Council of Trent led many more Europeans to individualized relationships with Christian faith. This rise of individualism figured heavily in social theories of the late nineteenth and early twentieth century. The English civil wars limited the power of monarchs and prompted political theories about the basis of stable society. Thomas Hobbes' (1588–1679) *Leviathan* argued for a strong single ruler, but John Locke's (1632–1704) *Two Treatises on Government* (1689) argued for a 'social contract' between free individuals to jointly agree to be subject to the rule of law. Locke's vision of the person as a 'tabula rasa' contrasted both with Hobbes' view of 'the state of nature' as inherently brutal, and with Gottfried Leibniz' (1646–1716) later description of the human mind as innately capable of autonomous reason. Accounts of psychology's prehistory as a Locke–Leibniz debate make nature–nurture questions central but tend to obscure such theorists as Giambattista Vico (1668–1744) who emphasized how minds are shaped by history (see also Billig, 2008).

Philosopher-historian Michel Foucault (1926–84) described the seventeenth and eighteenth centuries as the period when 'the human' became an object of the sciences. In Britain particularly, systematic theories of the economy began to be theorized. The trend toward rational calculation of human life influenced the *utilitarian ethics* of Jeremy Bentham (1748–1832) in which pain and pleasure – not kings and queens – became the 'sovereign masters' of human conduct. The most radical effects of placing the rights-bearing individual at the center of social thought were the republican revolutions that formed independent nations in North America in 1776 and France in 1789.

The Origins of Disciplines in the Nineteenth Century

Nation-states relate populations of individuals to areas of territory. Nations are characterized by conflicting commitments to individual freedom and government, through the exercise of law. Three approaches to 'population' shaped social theories that predate the academic disciplines of sociology and psychology; statistical thinking, theories of evolution, and Hegel's dialectic. First the 1790 American census defined 'the people' as countable individuals whose 'will' the government would express. In nation-states, not all humans matched the narrow category of *the people* to be politically represented, in

gender, age, religion, or increasingly, in 'race.' In the United States, disputes about counting slaves, Native Americans, and immigrants proliferated. An explosion of statistical thinking in the 1830s saw the rising Bourgeoisie pondering aggregate rates of individual crimes and suicides. Adolphe Quetelet (1796–1874) observed that measures of individual physical attributes formed Gaussian distributions in aggregate, and specified median values as 'norms' (such as the 'body mass index' which still informs health psychology). Auguste Comte's (1798–1857) *Positive Philosophy* repeatedly imagined how such a science of society could rationally address the many social problems in France after revolution.

Second, Thomas Malthus' (1766–1834) *An Essay on the Principle of Population* of 1798 described population growth as geometrically increasing, food supply as arithmetically increasing, and demographic catastrophe as mathematically inevitable. Malthus influenced psychologist Herbert Spencer (1766–1834), whose popular works were celebrated in laissez-faire industrial Britain and later influenced early twentieth century social psychological theory. Spencer's works are often the target of critiques of 'social Darwinism's' Machiavellian attitude to the suffering and exploitation of the poor. Malthus did influence Darwin's (1809–82) theory of nature as a competition between individual organisms for survival in *The Origin of Species* (1859). The theory of evolution specified that variation was the raw material upon which natural selection acted to generate new forms, and that men embodied this variability more than women did (Shields and Bhatia, 2009). Darwin's cousin Francis Galton's (1822–1911) eugenic philosophy built on this idea in its proposals for societal improvement by increased reproduction among valued people, like political leaders and scientists, and by curtailing reproduction among the degenerate.

Finally, G.W.F. Hegel (1770–1831)'s *Phenomenology of Spirit* of 1807 described a dialectical process involving 'triads' in which self-consciousness emerges from its recognition by another in a power struggle, as that between a master and a slave. This 'dialectical' process was partially inspired by Hegel's observations of Napoleon's conquest of the Germanic states. The Hegelian suspicion of the unity of dominant knowledge created a doubtful orientation to all types of dominant knowledge. Karl Marx' (1818–83) dialectical *materialism* aimed to analyze and supersede the class conflict between capitalists and the proletariat created by nineteenth century industrialization. *The German Ideology* (1846) critiqued the 'false consciousness' of the ruling class who made their class interests appear 'natural,' Friedrich Engels' *The Condition of the Working Class in England* (1845) described the lived realities obscured by such false consciousness. Marx and Engels' *Communist Manifesto* (1848) was a blueprint for the revolutions of the twentieth century based on class consciousness. Hegel also informed W.E.B. DuBois' (1868–1963) *The Souls of Black Folk* (1903) and Simone de Beauvoir's (1908–86) *The Second Sex* (1949).

Psychology developed as a science of the individual mind in some isolation from these developments (Fancher and Rutherford, 2012). Immanuel Kant (1724–1804) insisted that the native human mind necessarily perceived the world through the constructions of its intuitions and categories. In the fertile environment of the German university system, this theory outlived Kant's own doubts about any possible empirical science of mind. Hermann Helmholtz (1821–94) timed the speed of the nerve impulse, Gustav Fechner (1801–87) graphed psychophysical relationships between physical stimuli and the sensations they produced, and Wilhelm Wundt (1832–1920) built an Institute for Experimental Psychology at Leipzig in 1879 which trained a generation of researchers who replicated psychological training in multiple locations. Wundt demarcated experimental psychology from *Völkerpsychologie*, the study of culture. Cultural 'thought' was not amenable to study via the individual mind in the laboratory, because it followed a different 'psychic' causality that allowed for creativity and emergence. A related distinction lays in Wilhelm Dilthey's (1833–1911) distinction between *Naturwissenschaft* (natural science) and *Geisteswissenschaft* (social science).

Wundt was rivaled by William James (1842–1910) who taught a pragmatist psychology in the 1870 and 1880s at Harvard, influenced by Alexander Bain on the cultivation of positive habits, and C.S. Pierce's on clear scientific theory and sustained logical thinking. James' *Principles of Psychology* (1890) describes the self as multiple and social, and his account has remained relevant to successive generations of social psychologists' theories of the self. James theory suggested greater unity between mind and society than Wundt's. He and other psychologists disapproved when Wundt's student, Hugo Münsterberg (1863–1916) distinguished the 'ideographic' and the 'nomothetic' to separate historical and psychological kinds of explanations as limiting psychological theory prematurely.

Late nineteenth century French social psychology was informed by Jean Martin Charcot's (1825–93) theory of *grand hypnotisme* describing susceptibility to hypnotism as a symptom of hysteria. Charcot's experiments were shown to be effects of unintended *suggestion*, but 'suggestion' a popular explanation of social influence and 'hypnotism' a metaphor for mindless suggestibility. Gustav LeBon's (1841–1931) *The Crowd: The Study of the Popular Mind* (1895) analogized the collective actions of crowds to the suggestible person under hypnosis, explaining why crowds appear to autonomously follow leaders. Gabriel Tarde's (1843–1903) *The Laws of Imitation* (1890) also used hypnotism to analogize social influence. Tarde's laws included *descent* by which 'inferior' classes imitate superior ones, *geometrical progression* by which ideas disseminate rapidly, and *the internal before the exotic* by which in-group members inspire more imitation than out-group members.

French theories of suggestibility were matched by William James' and others interest in the 'ideomotor action' by which the idea of an act might give rise to the act itself. Tarde's work was translated into English by psychologist James Mark Baldwin who had begun to describe imitation as the means by which children enter society. American economist Edward Alsworth Ross (1866–1951) 1908 *Social Psychology: An Outline and Sourcebook* theorized social behavior as a consequence of 'imitation' or 'suggestion' along French lines, expressing a hope that an individual might rise above these influences, 'to become a person and not a parrot' (p. 4). Ross emphasized the influence of social customs and individual leaders or 'great men.' His claims about Whites' 'race suicide,' and views that some races were more suggestible than others, mirrored the

class anxieties of the French, and reached the ears of United States leaders, as the country was increasingly thinking about its own population in eugenic terms.

LeBon also analogized the crowd mind to that of the 'primitive.' Unusual individuals in 'civilized' societies – such as 'Victor,' a 'wild boy' in Aveyron found in 1800 – had long raised civilized minds. During the late nineteenth-century period of European and American colonial expansion, theories about 'primitive' minds and societies proliferated to legitimate this unprecedented extension of global domination by the few. Physical measurement or *anthropometry* – as in the racist 'American school' of the 1830s, or the 1898 Cambridge Anthropological Expedition to Torres Strait – had limited theoretical scope to ground the category of 'race.' Edward Tyler's (1832–1917) *Primitive Culture* (1871) likened the minds of 'primitives' and children, and described 'primitive' animist beliefs that souls can inhabit things and be separated from bodies (Richards, 2010).

Twentieth-Century Social Psychological Theories

Sexuality, like primitivism, prompted particular anxieties about 'degeneracy' in the late nineteenth century. Sigmund Freud (1856–1939) theorized hysteria as an effect of repressed sexuality, to be revealed by analysis of dreams and symptoms. Freud's psychoanalysis had vast scope and regularly engaged the relationship between minds and societies. In *Totem and Taboo* (1913), Freud merged Locke's contract theory and contemporary anthropology to explain how laws emerged when a 'band of brothers' killed their father and repressed memory of the fact in agreement to share sexual rights to women and property. Here as elsewhere, women were secondary in Freud's theory even if they populated his consulting room (Gilman, 1990). Freud conceptualized the death instinct after World War I revealed unconscious compulsions to repeat among 'shell-shocked' soldiers.

William McDougall's (1871–1938) *Social Psychology* (1909) proposed an influential instinct theory for social psychology. Critical of utilitarianism, McDougall described pain and pleasure as mere indications of whether more basic instinctual drives such as fear, disgust, curiosity, anger, pugnacity, self-basement, self-assertion or the parental instinct were satisfied. Instincts might generalize, as through 'the sympathetic induction of emotion' by which an emotion is felt because it is observed in another. Both McDougall and Freud's theories of instincts were popular, but both drew criticism for their circular reasoning from behavior to taxonomies of hidden instincts and back again.

Several other influential social sciences theories of this period had comparatively *less* influence on social psychology. Émile Durkheim's *La Suicide* (1897) presented statistics to demonstrate how 'society' affected this most profoundly individual choice. Thorstein Veblen's *Theory of the Leisure Class* (1899), and Max Weber's *The Protestant Work Ethic and the Spirit of Capitalism* (1904) continued to bring historical explanation to bear on subjectivity but never became social psychology 'classics.' The absence of an influence of Marxism on American social psychology is notable, but the empirical tradition of making observations of the English working class continued, particularly with Charles Booth's *Life and Labour in London* (1902).

Finally, theories that separated the individual and society, such as Wundt's, influenced the form of social psychology taught in the Chicago philosophy department by George Herbert Mead (1863–1931) after 1901. Mead looked to Darwinism to avoid the teleology inherent in notions of historical progress in German theories. Building also on James and others, Mead described self-consciousness as arising from taking the role of another with oneself. At Chicago, contextual empirical studies of urban realities flourished particularly in the 1920 and 1930s under the leadership of Robert Park (1864–1944). More progressive theories of group differences emerged early on in this context. The *Polish Peasant in Europe and America* published 1918–20 by W.I. Thomas and Florian Znaniecki was influenced by anthropologist Franz Boas arguments against popular eugenics and notions of racial inferiority. Boaz and Thomas and Znaniecki examined the disruptive effects of urbanization and peasants' diverse 'attitudes,' although they did not measure 'attitudes' as later theorists did (Danziger, 2000a).

Social Psychology Theories between the World Wars

Social psychology increasingly aspired to address social problems between the World Wars. The scientific status of psychology in the United States was solidified by the rise of testing, measurement, and application, and behaviorist theory. In the 1920s, the measurement of individual attitudes, values, personality traits, and stereotypes all became more ordinary practices, and competing theories of what these constructs might be were generally occluded as they began to be measured with greater frequency and enthusiasm. Floyd Allport's (1890–1979) 1924 volume *Social Psychology* explained effects of suggestion and association in the behaviorist language of 'conditioned reflexes.' Allport defined the 'social' of social psychology in individualist terms, ruling out of court the idea that there was a 'group' level of description; which he described as a 'fallacy' (Danziger, 2000b). Freud's work stimulated a public appetite for psychological theory as sexual mores changed. Social theories, minds, and societies entered more active feedback loops particularly when social scientists were called upon to address social problems created by the great depression.

Theories of 'culture' and 'personality' put mind and society into theoretical relationships in ways that remained closely tied to psychoanalytic theory and practice rather than measurement. In 1928, anthropologist Margaret Mead (1901–78) published *Coming of Age in Samoa*, using variation in gender roles as 'negative instances' to disprove theories about universal human nature. Along with German émigrés such as Karen Horney (1885–1952), and American psychiatrist Harry Stack Sullivan (1892–1949), Mead and other anthropologists formed alliances around New York known later as 'the culture and personality school' whose members attempted to theorize modern subjective experiences of neurosis, anxiety, and freedom at the boundaries of psychiatry and the social sciences. Adolf Hitler's rise to power stimulated a very different need for 'cultural' explanation of consciousness and behavior.

At Frankfurt's Institute for Social Research, scholars such as Erich Fromm (1900–80) used Marx to theorize the problems of adjustment revealed by psychoanalysis as specific to capitalist societies. Fromm also contributed to the fertile culture and personality school, and his 1941 *Escape from Freedom* typifies a Marxist-Freudian style of historically embedded theory.

Hitler's rise to power in 1933 created a new form of dictatorship that stimulated a new interest in explaining 'suggestion' because of Hitler's effective propaganda. Prior to this, Gestalt psychology had flourished in Berlin, and psychologist Kurt Lewin's (1890–1947) attention was drawn particularly to social motivation (Ash, 1995). His 1935 *A Dynamic Theory of Personality* summarized 'field theory' – the most enduringly influential theoretical synthesis in social psychology from this period. Lewin specified that behavior was a function of a person and phenomenological proximal environment. Expressing a belief in the scientific status of measurement, Lewin's central axiom was expressed by a formula $B = f(P, E)$, used topographical diagrams to show which behaviors *could* occur, and 'vector psychology' to predict which behaviors *would* occur (Gold, 1999). The practical utility of this general theory seemed demonstrated by Lewin's own work on the effects of authoritarian, democratic and laissez-faire leadership. Muzafer Sherif's (1906–88) 1936 studies of conformity to group norms also expanded the concept of the 'norm' beyond sociology, toward something that could be manipulated in a situationist experiment to effect the behavior of individuals and groups. John Dollard (1900–80) and colleagues' *Frustration and Aggression* (1939) was a similarly situationist theory that drew on behaviorism, engaging Freudian concepts to theorize aggressive behavior as a form of drive reduction. By linking patterns of lynching to low cotton prices in the South it went beyond classic Lewinian theory in examining historical change as well as the individual's immediate 'environment.'

American Growth after World War II

The resolution of World War II led to unprecedented international efforts to bring about enduring peace that looked to the 'social sciences' rejections of the notions of race differences and aggressive instincts. A 'cold war' between the United States and the Union of Soviet Socialist Republics described by Eisenhower as a 'battle for hearts and minds' drew military defense and psyche closer together. Psychological research was generously funded by military organizations, private foundations, and the National Science Foundation, and grew in the United States to a totally unrivaled degree. Textbook publication in social psychology accelerated accordingly.

Theories of mind and society became increasingly mathematical and statistical. Influential theories that aimed to put the social sciences on mathematical footing included Von Neumann and Morgenstern's game theory, Shannon and Weaver's theory of communication, and systems theory. Psychologists more frequently used Ronald Fisher's inferential tests to stabilize doubt about the similarity or difference between groups in experiments. The 'construct validity' of tests was described by psychologists Lee Cronbach and Paul Meehl in 1955, curtailing faith in many popular interpretive projective tests. 'Variables' were increasingly theorized as existing in people prior to being observed, unlike the earlier operational understanding of variables as things that psychologists would 'vary' to produce experiments.

In this context, smaller theories developed with less ambitious scope and a closer relationship to experimental test. An early example is Carl Hovland's (1912–61) theory of persuasion as a process that occurred between a *communicator*, *communication*, and *audience*. Theory was increasingly tested in increasingly theatrical experiments, requiring more frequent deception of participants, and decreasing numbers of reminders – such as Hovland's (1959) – that the laboratory and the real world might be different from each other. The now-classic textbook theories and experiments date particularly from the 25 years after WWII; Solomon Asch's experiments on conformity, Muzafer and Carolyn Sherif's theory of realistic group conflict, Leon Festinger's theory of social comparison. British social psychologist Michael Argyle (2001) recorded being impressed by the United States culture of ingenious experimentation but also unsatisfied by its artificiality. Historian Frances Cherry (1995) described how implicit theoretical commitments can be gleaned from reading research from this period with an eye for the authors' troubled attempts to exclude 'stubborn particulars' from abstract experimental designs.

Prejudice became a new phenomenon to explain. Kenneth and Mamie Clark's study showed a preference for White dolls among Black children, and influenced the 1954 *Brown vs Board of Education* United States Supreme Court decision to desegregate schools and other institutions. Earlier theories about race and culture differences ceded to theories that explained belief in race difference as a form of *prejudice*, driven by authoritarian personalities in Adorno, Frenkel-Brunswik, Levinson, and Sanford's *The Authoritarian Personality* (1950), or the intersection of personality with stereotyping in Gordon Allport's *The Nature of Prejudice* (1954).

Milgram's notorious demonstration of obedience to authority emerged from this context. In Milgrams' experiments, experimental variables were manipulated affecting the extent to which naïve subjects would be willing to obey an experimenter's authority and to deliver what appeared to be lethal electric shocks to a stranger in an adjacent room. Milgram (1974) presented his work as an explanation of the banality of evil shown during the Holocaust. In his account, it was not authoritarian personalities, or German culture that could explain this most unfathomable of historical events. Rather, forces in the immediate social situation, comprehensible as vectors in Lewinian fields, held explanatory theoretical value.

Theories of the constructive active person were suggested by Lewin's theory by virtue of its phenomenological roots. Social psychological theory of this period was responsible in part for the slow shift away from behavior toward cognition as the object of theories to be tested by experimental psychology. In the early 1960s, the theories of Jean Piaget, the first English translations of Lev Vygotsky, and Bandura and Walters 'socio-behaviorist' theory of how children learn through observation all suggested a more active child than the tabula rasa of John Watson's behaviorism. Theory was increasingly understood as developing through hypothetico-deduction rather than induction, as philosophers such as Karl Popper and Thomas Kuhn critiqued the logical positivist assumption that induction and observation moved scientific theory forward. Leon Festinger's

theory of cognitive dissonance stimulated enthusiasm for experiments to test competing theories. Festinger theorized 'cognitive dissonance' as an unpleasant arousal state brought on by 'dissonant' thoughts, or dissonance between a thought and an action. Early experiments demonstrated the failure of parsimonious behaviorist theory to explain changes in attitudes without recourse to a need for 'dissonance reduction.' For example, Festinger and Carlsmith showed that young men reported linking a boring task particularly after they were given an insufficient monetary reward for leading another student to engage in it. However, Daryl Bem's 1967 self-perception theory invoked Occam's razor against Festinger's theory. Bem showed that some experimental results explained by 'dissonance reduction' could be attributed to the more simple process by which people infer their own attitudes from their behavior as if they were observing that behavior in another person. Several attempts to construct critical experiments to test the two theories followed.

Crisis and the Rise of Attribution Theory

The unprecedented growth of experimental social psychology prompted interrelated 'crises' toward the end of the 1960s (Collier et al., 1991). The first issue concerned the construct validity of experimental methods. Drawing on hypnosis studies, and echoing the questions that stalked Charcot, Martin Orne theorized the 'demand characteristics' by which participants try to fulfill experimenter's expectations of how they should act, as in Milgram's experiment, for example. Rosenthal and Rosnow (1969) showed dramatic unintended effects of such expectations on the results of human and animal experiments.

Second, the ethics of experiments, such as Milgram's, that deceived participants about purposes and procedures divided researchers. Some were happy to design experiments that scripted the use of electric shocks and orders to eat cockroaches, but Kelman's 1967 critique described deceptive methods as unethical and undermining of trust in institutions. Third, the *relevance* of theories and the shrinkage of theoretical ambition prompted anxiety, as debates about dissonance and attitude change led researchers to conduct 'experiments about experiments' rather than experiments about phenomena. Finally, Kenneth Gergen (1973) convincingly argued that history could modify all attempts to find universal laws of social behavior at the Lewinian level of analysis.

During this growth period, specifically *sociological* social psychologies grew more slowly and did not participate in the same level of crisis. Under Herbert Blumer's influence 'the Chicago school of symbolic interaction' emphasized how people act on the basis of meanings arising during social interaction and modified through interpretation. Symbolic interactionists eschewed quantification for reflexivity; insisting that research was also a process of symbolic interaction that social scientists must approach via 'sensitizing concepts.' Psychologists were most influenced by the writings of Erving Goffman (1922–82) among sociologists of this period. More skeptical approaches to generalizable social theory such as Glaser and Strauss' grounded theory, Harold Garfinkel's ethnomethodology, or Berger and Luckman's social constructionism influenced only those psychologists most determined that the crisis in experimental social psychology was a insurmountable.

Within the United States, *attribution theory* emerged as the theory to test experimentally from the crisis, shifting attention from the behavior of the person in the situation, to the cognitive *attributions* for behavior to either the person or the situation. Kelly's theory of covariation analysis (1967), Jones and Davis' *correspondent inferences* (1965), Jones and Nisbett's actor-observer effect (1972), and Ross (1977) *fundamental attribution error* kept Lewin's formulations central to social psychology, and responded to all four aspects of the crisis. Experimental methods could now claim to access cognitive meaning-making just as symbolic interactionists might do. Pencil and paper measures of attribution raised fewer ethical risks of earlier experiments on dissonance, or obedience. By describing people's behavior as subject to attributional 'biases' away from rationality, the theory implicitly argued for the relevance of a scientific study of social behavior to everyday life. Indeed, psychologists picked up their statistical tools and made theories of them, most obviously in work on judgment and decision-making such as that gathered in the 1982 Kahneman, Slovic, and Tversky volume, *Judgment Under Uncertainty; Heuristics and Biases*. During the 1970s and 1980s, cognitive theories were applied to an ever-widening range of objects in American social psychology, particularly the self. Theories of self-schemas, self-presentation, self-discrepencies, self-affirmation, and possible selves flourished in the 1980s, often looking back to James, Baldwin, and Mead, but always imagining the self as an individual cognitive representation, however the contents of that representation might originate in some 'social' field. The self was increasingly theorized as relevant to health; optimism; and 'positive illusions' were healthy, as in James' pragmatism. Troubling claims about individualism were largely ignored by 'social cognition' theories (Pepitone, 1981), but growth in social psychology elsewhere troubled their foundations.

European independence from culture-bound individualist American theories was formally declared by Israel and Tajfel's *The Context of Social Psychology* (1972). European social psychological theories tended to reject the valorization of the individual over the collective mind. First, Serge Moscovici's *La Psychanalyse, son image, son public* (1961) had introduced 'social representations' which used Durkheim to theorize the relationship between individual and collective representations, focusing on how specialized knowledge becomes widespread and shared. Second, in 1971, Tajfel published, with others, 'Social categorization and intergroup behavior.' A rejoinder to Sherif's (1966) Realistic Group Conflict theory, Tajfel's 'minimal groups' experiment showed that people would sacrifice total net gain to express a discriminatory prejudice in favor of their in-group over an out-group. The minimal groups experiment anchored Tajfel's Social Identity Theory of how individual's behaved differently because of their status as group members (Brown, 2000). Third, Rom Harré's 'ethogenic' approach to social observation drew on Goffman and other sources to describe how meaning is made up in real social environments. Marsh, Rosser, and Harré's study of violent group behavior during British soccer matches; *The Rules of Disorder* (1978) described collective behavior as ordered in

ethogenic terms rather than as a 'deindividuated' crowd of LeBon's sort.

In recent decades, theorists have varied as to whether they seek to explain the age-old disparity between attitudes and behavior, or to deconstruct it. The theory of reasoned action resolved the problem of predicting behavior from attitudes by theorizing a moderating effects of subjective norms between the two, becoming a hegemonic unifying theory of health interventions. In contrast, discourse analysis and discursive psychology have tended to deconstruct the boundary between attitudes and behavior. Following Ludwig Wittgenstein, British ordinary language philosophers withdrew interest in the 'truth status' of language, describing words as forms of action. This understanding informed Jonathan Potter and Margaret Wetherell's argument in their 1987 book *Discourse and Social Psychology*, that attitudes were of interest to social psychologists only when expressed in discourse, and hence were actions or 'behavior' in their own right. In contrast to dissonance theory, discourse analysts insist that talk is riven with contradiction that people barely notice, and 'discursive psychology' extended an understanding of social psychology without variables to memory, self, gender, and other topics (Potter, 2011).

By the 1990s, theorizing became more global as Asian experimental social psychology expanded and classic North American theories were shown to be culturally particular as in Joan Miller's early study of attributions among American and Hindu Indian adults and children. 'Universal' theories of social psychology developed within Western Industrialized Educated Rich and Democratic (WEIRD) nations are actually culturally particular. Theorists now often strive for innovation by abandoning the privileged position that WEIRD nations have in theoretical formations, as Moghaddam (2013) has recently done with democracy. Contemporary attempts to use the distinction between 'individualist' and 'collectivist' countries as a unifying framework for cultural psychology have garnered significant critique.

Simultaneously, the embodied organism has returned to challenge social cognitive theories. Instinct theories returned through evolutionary psychology, following Leda Cosmides' (1989) argument that humans evolved to reason about Locke-style social contracts. Explanations of autistic people as lacking a 'theory of mind' linked social cognition and neuroscience, focused attention on the mirror neuron system as the embodied basis of social cognition that resemble James' ideomotor action, Baldwin's imitation, and McDougall's sympathetic induction. Currently experiments showing how the implicit meanings of stimuli are evident in embodied ways are favored.

Conclusion

We conclude that unity in social psychology theory is an animal often stalked but rarely captured. Among social scientists, social psychologists have been relatively untouched by dialectical theories that emphasize how all types of dominant knowledge come to self-consciousness through conflict with their 'others' (Liu and Liu, 1997; Plon, 1975). However, hegemonic theories from Lewin's field theory to Festinger's cognitive dissonance have recognized individuals as being moved by environments in dialectical ways to new self-understanding and conduct. We cannot conscientiously say what theories would be possible if this irony in the science of social psychology were made more explicit.

Abstract

The historical roots, conceptualizations of the discipline, research practices, and institutional support of social psychology are discussed herein. This article attempts to present the discipline and the particular way it looks at phenomena that are simultaneously individual and social. Social psychology is considered as an interdisciplinary science that challenges the distinction between the individual and the social, and is an empirical science with diverse methodology and important applications.

How to Define an Area of Theoretical and Empirical Interest?

Many social psychologists, when asked about their job, must have faced the awkward situation of having to define the discipline to nonpsychologists. People seem to more or less understand what psychology is about (although this representation may be limited to what clinical psychology does) and what sociology does. However, they have difficulty in figuring out what social psychology is. Moreover, in their attempt to explain what they do, social psychologists are often either too precise, describing their own area of expertise, or too broad, speaking about "phenomena relating to people in groups and social categories." This difficulty is not due to the vagueness of the discipline or to the incapability of social psychologists to give a comprehensive definition of their area. This difficulty is common to the definition of every abstract notion and depends very much on the way a community describes and prescribes the issues that concern it. This difficulty relates to the history of social psychology community, its traditions and practices, and the institutions that support its existence. In other words, it is also difficult to define the content of the category as being 'American' or 'French' or 'Greek.' For this we rely on the consensual and contested understandings of the community of people that define themselves as such, their common history, practices and traditions, and the legal and institutional ways that recognize their existence. Such definitions are both descriptive and prescriptive. Social psychology, therefore, can also be defined by the way social psychologists understand and approach their area of expertise, its historical roots, its empirical traditions and practices, and the way institutions recognize it. In this article these issues are briefly discussed in order to present what social psychology does and to connect it with the social psychological articles in this volume.

Historical Roots and the Development of a New Scientific Endeavor

Before considering the definitions that social psychologists give, it is important to talk about the historical roots of this discipline. Social psychological phenomena were experimentally researched at the end of the nineteenth century and in the early years of the twentieth century. Triplett (1898) in the United States and Ringelmann (1913) in France researched the effect of the presence of others on the outcomes of individual or collective work. Triplett, with the *social facilitation effect* (term attributed to the effect by Floyd Allport in 1924), demonstrated that the mere presence of others increased individual performance, whereas Ringelmann showed that individual members of a group become less productive as the size of their group increases. Both of these phenomena, showing the importance of the presence of others in individual behavior, were further researched by many social psychologists.

These experiments were carried out in a period in which there was a great deal of interest in developing and increasing people's performance at work. Social psychology is very much linked to societal questions and concerns that lead to empirical research and theoretical developments. In a period of industrial development where the focus was on performance at work, Mayo (1945) proposed that social motives could also increase people's performance, even under poor working conditions, if workers made sense of the situation as a demonstration of interest on the part of their employers (Hawthorne effect). Thus, the way people make sense of a particular situation impacts their behavior. These early experiments can be considered as the first social psychological investigations where the presence of others (real or symbolic) and the meaning given to a particular situation influenced individual behavior.

The late years of the nineteenth century were also characterized by the work of Le Bon (1895) (*see* Collective Behavior, Social Psychology of; Social Movements: A Social Psychological Perspective; Deindividuation, Psychology of) and Tarde (1890, 1898), who greatly influenced social psychological work on masses and social influence. In this period when the masses came to the forefront of history, the work of Le Bon characterized crowds and collective behavior as irrational in comparison to the rationality of individual behavior, and the work of Tarde restricted influence to imitation. The division between the individual and the collective was established and continues to haunt social psychology. Even so, both scholars claimed that there are phenomena that could not be approached in a similar way to the one used for individual behavior.

For many, Wundt's *Völkerpsychologie* (1900–1920), with its interest in customs, language, and practices, is also viewed as a precursor of modern social psychology (Doise, 1995; Farr, 1996). Wundt's work influenced many American psychologists who came to Europe between 1865 and 1914.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24095-6

Farr (1996: p. 36) observes: "the inheritance from Wundt was an experimental psychology that was not social and a social psychology that was not experimental. If psychology first became an experimental science in Germany, then it was social psychology that became an experimental science in America."

Modern social psychology owes much also to the work of French sociologist Emile Durkheim, who in the second edition of his book on the division of labor in society (1893) asks a profoundly social psychological question: "What explains the fact that while becoming more autonomous, the individual becomes more closely dependent on society?" (cited by Doise, 1995). From the Durkheimian concept of collective representations, Moscovici (1961/76, 2008 for the English edition), later, develops the concept of social representations that continues to attract social psychologists around the world (*see* Social Representations). Two textbooks of social psychology were published in 1908, in Britain by McDougall and in the United States by Ross, testifying that this new discipline was born. During this period in the United States, Floyd Allport dominated the field, expressing an individualist, positivist, and behaviorist approach to the study of social psychological phenomena.

What we can learn from this brief account of the very early days of social psychology is that, contrary to assumptions (Jones, 1985/1998), the discipline developed on both sides of the Atlantic with scholars trying to understand the relationship between mind and society, the individual and the social. These early days were characterized mainly by behaviorist influences dominant in psychology at the time.

This dominant behaviorist approach was challenged by social psychologists, many of whom fled Europe in between the two world wars and developed a social psychology influenced by the Gestalt. Indeed, in the 1930s many social psychologists moved to the United States and brought with them a tradition of research influenced by the Gestalt, where relationships were the focus of attention. Koffka's *Principles of Gestalt Psychology*, for example, introduced this approach to an American public. A very prominent figure for social psychology was Lewin (1936), who proposed that behavior was a function of the interaction between the person and the environment. He applied this equation in the analysis of group dynamics and was one of the first to point out that a group is not the mere sum of its members. This approach was echoed by other social psychologists like Muzafer Sherif (autokinetic effect, 1935), who showed that norms were developed by groups in response to uncertainty and that they were collective outcomes beyond individual members' decisions. This approach was also important in the development of Heider's theory of causal attribution, balance theory, and interpersonal relationships (1958) and Asch's Impression Formation (1946). The Gestalt theorists established social psychology as an empirical and experimental science, emphasized relationships, and moved the focus of attention from behavior to social perception, albeit "Individualizing the Social" according to Farr (1996). At the same period, George Herbert Mead's courses, later published (1934) in *Mind, Self and Society*, established symbolic interactionism as an important field in social psychology and introduced the self as a social mediator between the mind and society. In this prewar period, social relationships and interactions emerged and became the focus of attention of social psychological work. Social psychology oscillates between an emphasis on individual behavior and the importance of the social context in which actions and relationships take place. This is the time when a clear division appeared between what is called a 'psychological' social psychology and a 'sociological' social psychology. It is also the time when experimentation was linked to social psychology as a defining feature of the discipline.

During World War II, much work was devoted to the study of the attitudes, thoughts, feelings, and adjustment of the soldiers. The *American Soldier* (Stouffer et al., 1949) was an immense research project that sealed the link between social psychology and the military, who continued to fund research and was instrumental in the development of social psychology on both sides of the Atlantic (Moscovici and Markova, 2006). The war created political pressure for action research, and Lewin's work (1947) on reorienting food habits away from food shortages to help with the war efforts is considered as an application of social psychological work on group dynamics.

Social psychology developed rapidly in the early years after World War II. The world was horrified by the brutality of the war and wanted to understand how this was possible. In the 1950s, Hovland at Yale researched propaganda, and Asch conducted his famous experiments on majority influence (*see* Persuasion Theories; Attitudes and Attitude Change). Adorno et al. (1950) studied the development of the "authoritarian personality." Also in 1952, Asch published *Social Psychology*, in which he set the goal for scientific research in psychology "to establish functional relations between conditions in the surroundings and psychological processes and between one psychological process and another" (p. 8). The appearance of Heider's book on interpersonal relationships (1958) and the famous Robber's Cave experiments (showing that the type of interdependence between groups impacts on social perception and behaviors) by Sherif et al. (1954) kept alive the Gestalt tradition in social psychology. Festinger's cognitive dissonance theory (1957) surprised the field and reversed the attitude–behavior relationship. This is the time (1966) that the European Association of Experimental Social Psychology (EAESP) was created with the support of American funds and efforts (Moscovici and Markova, 2006).

In the 1970s and the early 1980s, social psychologists continued the postwar tradition and were still interested in understanding prejudice and discrimination. Moreover, the famous Milgram experiment on obedience (*see* Obedience: Social Psychological Perspectives) made social psychological research and practices well known to the general public. In the presence of movements such as for civil rights, new themes emerged relating to group behavior and social change. Intergroup relations research by Henri Tajfel's team in Bristol (UK) and minority influence research by Moscovici in the Ecole des Hautes Etudes en Sciences Sociales in Paris marked the field and still continue to inspire research (*see* Intergroup Relations; Social Influence, Social Psychology of). Tajfel and colleagues were interested in understanding social change that occurred when people identified with social groups and acted as their members. They developed the notion of social identity that mediates the relationship between the individual and the group and is responsible for collective behaviors (*see* Social Identity in Social Psychology; Identity and Identification). In

Europe, in addition to minority influence research, Moscovici developed the concept of social representations from the Durkheimian concept of collective representations in order to understand social change. He was interested in how science becomes common sense, and how social knowledge develops and allows communication, conflict, and consensus to emerge (*see* Social Representations). Even today, these schools of thought continue to inspire research not only in Europe and the United States but also in Australia and Latin America.

This period also saw the rise of social cognition. This approach soon became dominant and helped social psychology to overcome its behaviorist past. Undoubtedly, social cognition contributed greatly to the study of social perception (*see* Social Cognition; Stereotypes in Social Psychology; Heuristics in Social Cognition). However, although it allowed psychology to overpass its behaviorist past, soon, by following the metaphor of the computerized mind became too individualized and social psychology was accused of having lost its societal grounding. Social cognition was criticized as ideologically driven, presenting an individual thinker whose cognitions defined the world, a cognitive miser, biased, using shortcomings to perceive and decide (Sampson, 1981). In 1972, Israel and Tajfel edited *The Context of Social Psychology: A Critical Assessment*, in which many prominent scholars tried to explain the distance that separated social psychological work from the social context. The publication of *The Social Dimension* in 1984, edited by Tajfel, was another attempt to find the lost 'social' in social psychology. These debates are still alive today in the social psychological community. It is also in this context that social psychology was challenged by cross-cultural psychology, when, for example, in 1988 Jahoda "accused" social psychology of being blind to cultural context and influences (*see* Cross-Cultural Psychology). In the same period, social constructionist approaches (*see* Social Constructionism) challenged the epistemology and methodology of the dominant sociocognitive approach and developed a series of social psychological investigations using qualitative methodology (*see* Social Psychology: Research Methods).

Our discussion of the current era of social psychology is purposefully brief. It is impossible to do justice to all theoretical accounts and to mention all the scholars who do social psychological research. This can be seen in the different articles of this encyclopedia. Moreover, this brief historical narrative cannot be exhaustive. Interested readers can consult the many historical accounts (e.g., Doise, 1995; Farr, 1996; Papastamou, 2002), and the article Social Psychological Theories, History of. An interesting account of the genesis of social psychology is proposed by Moscovici and Markova (2006) who, along with the theoretical developments, present the institutional construction of social psychology based on archival data. The purpose of our brief presentation is to give the reader the opportunity to trace the steps of social psychology in order to understand its current status and to grasp its domain.

The Domain of Social Psychology

As we have seen, over the years social psychology developed as an empirical, mainly experimental, science, emphasizing individual behavior and cognitions in context. Two brothers were instrumental in defining the discipline: Floyd and Gordon Allport. In 1924, Floyd Allport published a book on social psychology where he gave the following famous definition of the field (p. 4):

> There is no psychology of groups which is not essentially and entirely a psychology of individuals. Social psychology must not be placed in contradiction to the psychology of individuals; it is a part of the psychology of the individual, whose behavior it studies in relation to that sector of his environment comprised by his fellows ... There is likewise no consciousness except that belonging to individuals. Psychology in all its branches is a science of the individual.

Floyd Allport was clearly suggesting that social psychology is not an interdisciplinary field but a subdiscipline of psychology. His definition was instrumental to individualistic accounts and to the ideologically driven denial of society as anything more than a collection of individuals. Thirty years later, his brother Gordon Allport (1954, p. 5) gave another definition that is perhaps still the most cited definition in textbooks of social psychology:

> With few exceptions, social psychologists regard their discipline as an attempt to understand and explain how the thought, feeling and behavior of individuals are influenced by the actual, imagined or implied presence of others.

This definition puts processes of social influence and social perception to the forefront of social psychology. However, the individual still remains preeminent and many collective processes of knowledge production and social action are not included in this account.

The emphasis on the individual can be overcome if one articulates different levels of explanation, as proposed by Doise (1986). He suggested that social psychologists use different levels of explanation to make sense of the phenomena they study: (1) an intraindividual level where phenomena are explained by internal individual processes (see, for instance, categorization); (2) an interindividual and situational level where the dynamics of interaction between individuals explain the phenomena; (3) a positional (or intergroup) level where the explanation focuses on the position and status of individuals as members of groups with asymmetrical relationships; and (4) an ideological level where the explanation is based on the systems of social beliefs, representations, evaluations, and norms. In a more recent account of the levels of explanation, Doise (2012) adds two further levels: one where the explanation concerns biological accounts such as those used in social neuroscience studies, and a societal level, which includes explanations based on norms that function at a societal level such as human rights.

More than a typology of explanations, Doise's contribution to the definition of the domain of social psychology is his claim to articulate the different levels of analysis and explanation in order to avoid reductionist accounts of the different phenomena (*see* Levels of Analysis in Social Psychology).

Until now we have tried to circumscribe the domain of social psychology by presenting an historical account, famous definitions, and different levels of explanation. The difficulty with social psychology is that it deals with phenomena that are simultaneously psychological and social. What makes them so is perhaps the particular way social psychologists look at them. In 1988, Moscovici suggested that what differentiates social psychology from other disciplines is not its object but its particular gaze to phenomena and to the relations among them. Its particularity is to substitute to the binary relationship between a subject and an object into a three-party relationship: individual subject (Ego), social subject (Alter), and object (see **Figure 1**). This corresponds to a constant mediation that the social subject (Alter) performs. This relationship between the two subjects (Ego and Alter) impacts their relationship to the object and can be a simple copresence (as in the social facilitation effect presented earlier) or an interaction (as in the case of social influence).

For example, the relationship of an individual to his/her performance could be mediated or moderated (interaction) by the presence of others (real or symbolic). Moreover, interestingly, in the place of Ego and Alter one can substitute the individual with a group. This three-party gaze proposed by Moscovici makes the phenomena simultaneously individual and social. In recent years social psychologists have used this three-party relationship to explain, for instance, minority influence (Mugny, 1982) and politicized collective identity (Simon and Klandermans, 2001). If people look carefully at the work of social psychologists, they will notice that many concepts (like identity) act as mediators and that social psychological hypotheses are often hypotheses of mediation or moderation (*see* Social Psychology: Research Methods). Moderation and mediation hypotheses always involve three factors. In the case of moderation/interaction, the level of the third factor (the moderator) changes the relationship between the other two factors (the relationship between ego and object). This is a hypothesis of interaction that is usually formulated to answer a 'When' question: *When* would individuals be more prejudiced toward out-group members? When their in-group is of high or of low status? A hypothesis of mediation implies that the relationship between two factors depends on (is created by) a third factor. This hypothesis replies to questions of 'how' and 'why': *Why* people are prejudiced toward out-group members; it is because they identify with their own group that they wish to favor. These are simple examples, but social psychological literature is full of such hypotheses and sophisticated statistical techniques allow their testing (Baron and Kenny, 1986).

Figure 1 Moscovici's social psychological gaze.

From the previous discussion, we could say that the domain of social psychology is characterized by different levels of explanation whose articulation is aimed and by a particular gaze to phenomena that involve relationships of mediation or moderation. Within this framework, social psychological work aims to understand social perception, individual and collective behaviors, processes within groups, processes between groups, intraindividual and interpersonal processes, the production of social knowledge, ideologies and processes of communication, persuasion, and influence in order to understand how individuals and societies develop and change. To do so, social psychologists have elaborated concepts such as attitudes, stereotypes, social categories, beliefs, norms, identities, values, motives, collective memory, and social representations in order to approach different phenomena. There are articles in this encyclopedia concerning all these concepts.

Over the years social psychologists have worked on: intergroup relations, tyranny, sexism, racism, prejudice, leadership, decision making, risk, love and attraction, immigration and ethnicity, acculturation, prosocial behavior at an individual and intergroup level, aggression, conflict, xenophobia, dehumanization, stigma, obedience, collective behavior and action, social movements, mass killings and genocide, obedience, justice issues, and desegregation. For all these themes, there are specialized articles in this encyclopedia. There are also articles of theoretical interest to social psychologists such as about social cognition, social categorization, self-categorization theory, social attribution, essentialism, social constructionism, social representations theory, and cognitive dissonance.

Moreover, besides sociology and psychology that are part of its identity components, social psychology is closely linked to cross-cultural, indigenous, and political psychology. Culture and politics are two different fields within which social psychological phenomena evolve, and often social psychologists are interested in specializing in these areas. Thus, the interested reader can also find articles on cross-cultural and cultural psychology, indigenous psychology, culture and the self, culture and emotions, interpersonal relationships and culture, and political psychology.

Some questions that social psychologists try to answer are:

- How people understand and construct their social reality?
- How they feel in their environment?
- What motivates their actions?
- How and when they act together?
- The consequences of these actions?
- How people and groups influence each other?
- How people and groups produce knowledge norms and artifacts?

Social Psychological Practices, Ethics, and Institutional Recognition

From its very beginnings, social psychology was conceived as an empirical science. Initially, social psychology was mainly

experimental. This practice formed generations of social psychologists and characterized the discipline. There has been, however, criticism about the preponderance of experimentation (see also Gergen, 1973, 1995), and the development of social constructionist approaches opened the field to qualitative methods and epistemology. Moreover, survey methodology has been widely used and sophisticated statistical techniques have been developed to test social psychological hypotheses (for a comprehensive account, *see* Social Psychology: Research Methods). Nowadays, social psychologists use a variety of methods including techniques of neuroscience. Social psychological research is no longer characterized by a particular methodology. What does characterize the discipline is the importance that is given to empirical findings either to test a theoretical hypothesis or to help develop new theories.

The use of experimentation with human participants raises ethical issues. These concerns are raised in particular because experimental studies have sometimes used deception and not revealed initially to participants the real purpose of the study, in order to create the desired conditions of the social context. Famous studies such as the Milgram experiment and the Stanford Prison experiment by Zimbardo (1973) were criticized for the conditions to which they exposed their participants. Today, ethical concerns are very seriously taken into account, and ethical committees within universities review research projects and make sure that all ethical standards are kept. Important steps are taken to get participants' informed consent and to fully debrief them at the end of the study. Associations and academic societies have been involved in making public ethical codes of conduct (examples of these codes of conduct for research are the American Psychological Association standard 8: research and publication http://www.apa.org/ethics/code/index.aspx?item=11 and the British Psychological Society http://www.bps.org.uk/sites/default/files/documents/code_of_human_research_ethics.pdf see also the site of the European Union http://ec.europa.eu/research/science-society/index.cfm?fuseaction=public.topic&id=1433).

Nowadays, there are also debates about replication issues, and journals devote special editions looking to strengthen the discipline by assuring replication (see, for example, a 2012 special edition of Perspectives on Psychological Science). However, for some types of contexts and methodologies, replication is not the important issue. What matters is the understanding of the relationships and the phenomena occurring in a particular context. Social psychology as an alive community of research practice will continue to discuss these issues and enrich the scientific process.

At an institutional level, despite the interdisciplinary nature of social psychology, most scholars work in psychology departments and are trained through a psychology curriculum. Social psychology courses are considered core modules in degrees of psychology. There are many associations and academic societies of social psychology that organize conferences, academic activities, and summer schools for young researchers, such as: *Society for Personality and Social Psychology*, *Society of Experimental Social Psychology*, *European Association of Social Psychology*, *Society for the Psychological Study of Social Issues*, *Asian Association of Social Psychology*, *Society of Australasian Social Psychology*, *Canadian Psychological Association: Social and Personality Section*, *British Psychological Society: Social Psychology Section*, *Association pour la Diffusion de la Psychologie Sociale*, and many national associations. Moreover, social psychologists publish their work in a multitude of journals (for example, *Asian Journal of Social Psychology*, *Basic and Applied Social Psychology*, *British Journal of Social Psychology*, *Canadian Journal of Behavioral Science*, *European Journal of Social Psychology*, *Group Processes and Intergroup Relations*, *Journal of Applied Social Psychology*, *Journal of Community and Applied Social Psychology*, *Journal of Experimental Social Psychology*, *Journal of Personality and Social Psychology*, *Journal of Social Psychology*, *Journal of Social and Political Psychology*, *Personality and Social Psychology Bulletin*, *Personality and Social Psychology Review*, *Social Psychological and Personality Science*). The multitude of learning societies and journals testify to the rich scientific environment of social psychology and the depth of institutional support it has.

Social Psychology: An Ongoing Scientific Endeavor

We set out to define social psychology using historical information, definitions, and conceptualizations of its domain by social psychologists, and by research practices and institutional recognition. What makes social psychology distinct is a combination of what it studies, how it studies, and the level of explanation it seeks. Social psychology is interested in understanding how people are transformed by society and how they transform society (Chryssochoou, 2004). It is interesting to study stability and change in societies through the study of processes that involve the interaction of the individual and the social groups. Hopefully, by the end of this article, the reader will understand that social psychology seeks to answer a fundamental question: why there is a conflict, a division between the individual and society. It, therefore, can be the science that challenges this division and as a consequence the ideology that it supports. It is the science whose studies are placed at a mesolevel of analysis that bridges the macrosocietal-cultural level with the micro-individual one. Through interactions, communication and influence processes, and through social actions, individuals and groups produce cognitions and representations that join the individual and the social. As Moscovici (2000, p. 114) puts it: *the field of social psychology consists of social subjects, that is groups and individuals who create their social reality (which is in fact the only reality), control each other and create their bonds of solidarity as well as their differences. Ideologies are their products, communication are their means of exchange and consumption and language is their currency*. Hopefully, the multitude of social psychological work at different levels of analysis will help to disentangle the processes involved and the contents produced in our complex societies.

Abstract

Sociological social psychology emphasizes the impacts of society on social psychological processes. There are three major perspectives in sociological social psychology: symbolic interaction, social structure and personality, and group processes. The symbolic interactionist perspective emphasizes the ways that individuals construct social reality through social interaction. Alternatively, the social structure and personality perspective emphasizes the relatively stable elements of social structure that impact interactions among people such as roles, statuses, and norms. Finally, the group processes perspective focuses on the ways that societal conditions are recreated in small group environments and how interactions in groups contribute to the maintenance of society. These perspectives are being extended to include the study of sociobiology, the intersection of social and biological conditions that impact social psychological process.

Three Faces of Sociological Social Psychology

Social psychology is the study of human behavior in a social context. Utilizing this definition, researchers from several fields may be considered 'social psychologists' but they approach the field in different ways and utilize different perspectives in their approach to the topic. Some psychologists, for instance, focus on the immediate social contexts of interactions in the study of social psychology while others focus on genetic or internal thought processes occurring during those interactions. They also employ specific psychological perspectives such as social learning theory. Sociologists employ different perspectives and methods in the study of human social behavior than psychologists and sociologists emphasize the societal conditions that impact social psychological dynamics. How, for instance, do people's position in society influence interactions in small groups? How do we learn social roles in society? Sociologists employ a cybernetic approach to social psychology in which individuals interact in ways that reproduce society and society impacts individual-level interactions through norms, roles, statuses, and other elements of society (**Figure 1**).

The three main perspectives in sociological social psychology include symbolic interaction, social structure and personality, and group processes (House, 1977, 1992). Symbolic interactionists traditionally employ qualitative methods to study the social construction of reality, the ways that individual interactions lead to the development of society (Berger and Luckmann, 1967). Social psychologists who employ the social structure and personality perspective typically utilize surveys and other quantitative research techniques to assess the impacts of society on individual-level thoughts, feelings, and behaviors once they have been produced. A third group of scholars in sociological social psychology emphasizes the study of societal processes during group interactions. In some cases, researchers examine how social conditions (e.g., status differences) impact interactions within the group. In other cases, these scholars emphasize the study of how status differences develop within groups. In this sense, groups represent a microcosm of larger society.

Figure 1 Linking levels of analysis in sociological social psychology.

The role of sociobiology in sociological social psychology has been growing over the last decade. Sociobiology is utilized both to understand the relative impacts of genetic dispositions on social psychological processes and to assess how social conditions may impact biological outcomes. Some social scientists have argued that characteristics such as intelligence quotients (IQ), for instance, are genetically determined (Herrnstein and Murray, 1994) while sociologists examine how social conditions impact those things or how humans may define those characteristics as more or less important in society.

Symbolic Interaction

Perhaps the earliest application of the sociological perspective in social psychology comes from the University of Chicago and the work of George Herbert Mead. Mead (1934) and other social psychologists utilizing this perspective employ the pragmatist school of thought from the Scottish moral philosophers such as David Hume and Adam Smith. This philosophy emphasizes reason and empiricism in the search for truth. As applied to the study of human interaction, symbolic interactionists focus on the study of day-to-day interactions rather than the discovery of abstract principles of large-scale social behavior.

Mead (1934) included elements of social learning theory in the development of symbolic interactionism in that humans learn social reality through observation and reinforcement. Children not only learn basic skills such as reading and writing through these processes but also roles and norms, the building blocks of society. Unlike the psychological applications of behavioralism, Mead emphasized the importance of agency, the ability to make independent decisions within the constraints of social conditions. From this perspective, humans are capable of continuity and change; people can choose to

learn and follow norms and roles of previous generations but they can also choose to modify those norms and roles or rebel against them altogether. In many cases, change and continuity are going on concurrently with some individuals (or groups of individuals) modifying existing conditions to various degrees.

While Mead is generally considered the father of the symbolic interaction perspective, the expression was coined by Herbert Blumer (1969). Blumer studied under Mead at the University of Chicago where he taught for 27 years (Rohall et al., 2013). He later took an appointment to the Department of Sociology at the University of California, Berkeley in 1952. Blumer argued that there are three principles of symbolic interaction. First, people create social reality through interaction among individuals. This principle simply states that there is no inherent meaning in any person, object, or behavior – names or labels and their value come from the negotiation of two or more people. Second, people utilize these names and labels to make decisions in life. It is in this sense that both social and physical elements of the world are socially constructed. Finally, Blumer argued that individuals engage in an interpretive process in which the meaning of a particular interaction may vary based on the background of the participants and other factors. If our social world is socially constructed, any number of factors may lead us to different assessments of a situation, including our unique socialization experiences as well as our application of agency.

Given the fluid nature of social reality, Blumer (1969) and other symbolic interactionists typically employ qualitative methods such as ethnographies and personal interviews to discover how individuals come to construct social reality and the processes that lead people to define and redefine important aspects of society (see, for example, Adler and Adler, 1994). Techniques such as the autoethnography give symbolic interactionists the ability to gain insights into meaning-making processes in everyday life (Anderson, 2008).

Just as we construct our social world, we also construct our sense of self through the same processes. Charles Horton Cooley's (1922) looking-glass self emphasizes how people develop their sense of self based on their perceptions of what other people think of them. Just like a mirror distorts images, however, we have a distorted sense of our self because we rely on our interpretations of people's response to us that may be more or less accurate. If we believe that others see us as good, we will believe that we are good and vice versa. Humans also have the ability to manipulate their self-image through a process called impression management (Goffman, 1959). Goffman argued that humans construct an image of themselves in different social arenas that people utilize to make decisions during those interactions. These images may or may not correspond with our sense of self but individuals generally accept self-presentations unless there is reason to believe otherwise. An individual at a party, for instance, may tell people that she is a doctor and people will generally believe her until there is evidence to show that she knows nothing about medicine, perhaps failing to answer a medical question.

Two significant theoretical strands employing the symbolic interaction perspective include identity and social identity theories and affect control theory. Identity theory focuses on the ways in which individuals construct their sense of self through interaction with other people (Burke and Stets, 1999; Stryker, 2002). Identity is defined as the sum total of an individual's roles, traits, and social categories. Individuals develop their sense of self based on their unique dispositions or set of traits – which may or may not be derived from our genetic makeup – but also statuses, roles, and social categories that derive from society. We develop our sense of self through the unique combination of roles and statuses but also by the ways in which we modify those roles and statuses utilizing agency. A similar theory, social identity theory, emphasizes the influences of group characteristics in identity formation (Hogg and Ridgeway, 2003; Tajfel, 1982). Once a group membership (e.g., race or ethnicity) is incorporated into one's sense of self, it initiates other social processes such as judgment of other social groups relative to one's own group. By accepting roles, statuses, and group affiliations, individuals develop a unique sense of self while maintaining important elements of society.

Affect control theory examines the role of emotions in identity processes. In this theory, people apply three sentiments to each person: relative goodness (evaluation), power (potency), and liveliness (activity) (EPA for short). Roles and statuses in society have differing EPA sentiments and serve as a way to evaluate our performance in those roles and statuses (Heise, 2007). An extensive Web site on affect control theory can be found at: http://www.indiana.edu/~socpsy/ACT/.

While most symbolic interactionists focus on individual-level interactions, some symbolic interactions have begun to apply the paradigm to study large-scale social processes such as cultural production and the use of culture once derived. Collective memory includes the shared beliefs about a person or event in society. They may include the memory of particular events that impact only a small number of people (e.g., something that happened at work) or large-scale social events such as the terrorist attacks in the United States on 9 September 2001. Symbolic interactionists examine how individuals in society come to define such events and categorize them (Fine and Beim, 2007). Examining the common narrative around the famous Lewis and Clarke expedition to the American frontier in the 1700s, Denzin (2007) argues that while most Americans categorize this journey as significant and positive in American history, the narrative of the journey can also be interpreted from the perspective of native Americans and others who may categorize the event as tragic, leading to the decimation of Native American life.

Gary Alan Fine has conducted numerous studies of the production of culture ranging from little league baseball teams to weather forecasting organizations (Fine, 2007, 1979). These studies show how individuals at the organizational level incorporate and manipulate larger cultural norms, values, and beliefs to meet the needs of the individuals within organizations. While some norms continue over time, as taught by existing members of an organization, new members introduce new norms while accepting or modifying some of the existing ones, helping to elaborate on larger processes of cultural change and continuity over time.

Social Structure and Personality

The second perspective in sociological social psychology is often referred to as social structure and personality (House, 1977,

1992). Scholars in the social structure and personality perspective generally concur with symbolic interaction principles but emphasize the relatively stable nature of society. Norms, for instance, may change over time but many of them remain over many years. As such, social psychologists can study their impacts on individuals utilizing quantitative methods like surveys and experiments.

House (1992) puts forth three major principles of the social structure and personality perspective. First, the components principle states that we must be able to identify the elements of society most likely to impact individuals' thoughts, feelings, and behaviors. These elements typically include statuses, our relative position in society, roles, expectations about how to act in those statuses, and norms, expectations about how to think, feel, or behave in a particular interaction. Other important components of social structure include social institutions and values. Social institutions are relatively enduring patterns of social behavior in society. Typical examples of institutions include family, work, government, education, and religion. Values are enduring sets of beliefs about the world. These are distinguished from attitudes or public opinion that may be more or less enduring. Many analysts, for instance, argue that Americans have a tendency to value independence and freedom to a greater degree than their peers in other countries (Bellah et al., 1996; Putnam, 2000). These values come from socialization and may impact interpersonal relationships above and beyond individual dispositions.

The proximity principle is based on the idea that people are most impacted by society through their immediate social surroundings (House, 1992). While large-scale events like an economic downturn may have consequences for everyone in society, its immediate impacts are not felt by each individual. Economic downsizing itself, for instance, may have no direct bearing on the mental health of individuals in society except for those individuals who are laid off as a result of the downturn. However, spouses and families of unemployed people may also experience some of its effects (see Dooley et al., 1988; Rohall et al., 2001). Society, from this perspective, primarily impacts social psychological dynamics when it has direct bearing on individuals or indirectly through social relationships with those people.

The psychology principle emphasizes the ways that individuals process proximal experiences. Self-esteem research, for instance, shows that reflected appraisals, our sense of how others view us, are as or more important to individuals' feelings of self-worth than self-perceptions, our observations of our own behavior and its consequences or social comparisons (Schwalbe and Staples, 1991). In this case, our interpretations of others' reactions to us are more important than social conditions themselves.

There are many theories that utilize the social structure and personality paradigm. Life course sociology, for instance, provides a framework for examining the impacts of large-scale social events on individuals in a scientific way (Elder, 1994). There are many facets to life course sociology but they can be distilled into four elements: historical and social contexts, timing, linked lives, and agency. Each birth cohort, people born around the same time period, is exposed to different sets of historical events. However, those events may not impact everyone in a cohort the same way. In his classic study of the Great Depression, Elder (1999, originally 1974) found that only families who were deprived (i.e., lost significant income) appeared to be impacted by the Depression. Further, most of those effects were felt through changing family dynamics. These findings reflect the proximity principle of the social structure and personality perspective in which we experience society – including historical events – through our immediate social environments.

The degree to which social and historical events impact individuals depends, in part, on their relative position in society and when it occurs in their lives. Rosenberg and Pearlin (1978) showed almost no relationship of socioeconomic status and self-esteem among youth (8–11 years of age) but the relationship of these variables became stronger with each successive age group (teenagers and adults). In this case, economic conditions were less relevant to the self-concepts of younger children in the study.

Events impact both people experiencing them and their families and close relationships. This relationship fits under the heading 'linked lives' because they connect or link us to the life events impacting other people. Gartner (2008), for instance, found that people who knew someone injured as a result of the 9/11 terrorist attacks in the US were more likely to disapprove of the president than people who did not know of any casualties.

Life course sociology also incorporates the concept of agency. People can react any number of ways in response to the same conditions albeit limited by those conditions. Deluca and Rosenbaum (2001) found, for instance, that students who worked harder generally did better in school compared to students who worked less hard. However, middle-class students appeared to gain more from their hard work than their peers from lower socioeconomic statuses. Agency may help to explain variations in how people respond to the same historical event.

Another theoretical application of the social structure and personality perspective is the stress process (Pearlin, 1989). The stress processes examine the relative impacts of stressors, resources, and social characteristics on mental health. This model tries to understand differential reactions to the same levels or types of stress (e.g., death of a loved one), representing the third principle of the perspective. In this case, people under distress may react differently to it based on access to things like social support or differing levels of mastery or sense of personal control. If someone with low mastery experiences a stressor, she may respond with greater distress (e.g., depression or substance abuse) than someone with higher levels of perceived control, ostensibly because she believes that she will overcome the problem. Similarly, people with greater access to support networks may respond better to stress than people with fewer supports (**Figure 2**).

The stress process also incorporates elements of the first principle of the social structure and personality perspective by highlighting the ways in which people with different background characteristics process stressful life events. For instance, people from lower socioeconomic backgrounds have both higher levels of stress (e.g., financial strains and poor living conditions) and poorer mental health (Aneshensel and Sucoff, 1996). There are also racial and gender differences in the stress process (Kessler and Neighbors, 1986; Robins et al., 1991).

Figure 2 The stress process linking the societal conditions to individual outcomes.

Other applications of the social structure and personality perspective employ multilevel modeling to precisely assess the relative impact of macro- and micro-level conditions that impact individuals in society. These studies employ techniques that allow researchers to separate the relative impacts of actual community conditions from the perceptions of those conditions. Research shows that perceptions of neighborhood conditions (e.g., levels of vandalism, litter, vacant housing) are associated with outcomes like depression (Latkin and Curry, 2003); these findings may reflect the fact that people in those neighborhoods also report fewer social supports to buffer the negative effects of living conditions (Ross and Mirowsky, 2008). Studies that have tried to separate actual community conditions from perceived conditions suggest that most of the impacts of actual community conditions operate through perceived conditions: the impact of living in a poor community appears to operate completely through perceptions of those communities such that people in poor communities report worse perceptions of those communities, which lead to lower levels of well-being (Ross, 2000; Turner et al., 2013). These findings reflect all three principles of the social structure and personality perspective because individuals' positions (i.e., income levels) and proximal environments are processed internally, impacting some people more than others.

Group Processes

The study of group processes emphasizes the ways that basic social processes operate in group contexts. Groups include two or more people who have some level of dependence on each other and small groups are fewer than 20; small groups differ from larger groups in their ability to yield face-to-face interactions among its members. Dyads are two-person groups while triads are three-person groups (Simmel, 1950). This distinction is important because it shows that increasing the size of group exponentially increases the number of relationships while decreasing the levels of intimacy possible in a group. Sociologists distinguish several other types of groups that may impact interactions within those groups. Primary groups include family and close friends who interact on the basis of emotional attachments while secondary groups are those groups we affiliate with to achieve a specific goal or goals (Cooley, 1909). Work groups, teams, and volunteer organizations may provide some emotional bonding but affiliations are more instrumental in nature than in primary groups. An extension of these types of groups is reference groups. Reference groups are ones that may not include any physical interaction but people still employ them in making decisions. Individuals may pay annual dues to an online organization, symbolizing its importance to the person, but never attend meetings or interact with other members of that group.

Sociologists emphasize the ways in which inequality develops within group contexts and how outside statuses impact group dynamics. Four basic processes involved in the study of inequality are power, status, justice, and legitimacy. Power refers to the ability to obtain what we want despite resistance while status is our relative position in a group. Justice refers to perceptions of fairness when distributing things within a group while legitimacy is the sense that distributions are fair, regardless of how much people get in a group. These processes are typically studied under two major theories: social exchange theory and status characteristics theory, both utilizing social experiments.

Social exchange theory is based on the principle that people enter groups that provide them some benefit and leave groups when they perceive that they are not receiving a benefit from them. This theory is essential to explaining why people affiliate with other people in the first place but it also explains why people end relationships. There are four principles of social exchange theory (Molm and Cook, 1995). First, individuals in a group must have some form of dependence on each other – the theory does not apply to aggregates and acquaintance relationships. Second, within groups, individuals act in a way that will maximize personal benefits for themselves. The third principle, also known as the 'reciprocity principle', states that individuals will continue relationships as long as they receive about as much from a group as they put into it. If one or more members of a group believe that they are contributing more to the group good than they are receiving, they will seek alternative relationships outside of the group. Finally, the 'satiation principle' states that the value of what is exchanged may be reduced over time, thus explaining why people may end relationships even if they perceive them to be reciprocal.

Social exchanges may be direct, between two people, or indirect, exchanges among three or more individuals (Emerson, 1992; Homans, 1946; Molm and Cook, 1995). We may work for someone in order to receive pay but people may also help strangers with the understanding that they may require services from a stranger in the future. In this way, society can be seen as a network of direct and indirect exchanges. Status characteristics theory (sometimes called expectations states theory) employs elements of social exchange theory to understand how inequality develops in groups and how social statuses such as race and gender can impact exchange processes themselves. Robert Bales and other sociologists (Bales, 1965; Borgatta et al., 1954) analyzed interactions within small groups and determined that individuals who contribute most to group goals tend develop leadership status within those groups. Status appeared to be exchanged for service within the group.

Status characteristics theory focuses on the ways that outside characteristics influence status processes within groups (Blau, 1964; Berger et al., 1966, 1972; Lucas, 2003). Different status characteristics may influence the group, depending on the type of status. Specific status characteristics include those statuses that are important under specific conditions while diffuse status characteristics are those statuses that may influence the outcomes of all

exchange relationships. A mechanic may have high status among people who need their cars repaired but have no influence among a group of tennis players. Diffuse characteristics typically include individuals' sex and race that are believed to influence status dynamics in almost any group setting.

Sex status is one of the most widely studied areas of status characteristics theory. Research regularly shows that women receive less status than men in exchange relationships, even when they contribute most to the group (Lucas, 2003; Ridgeway and Diekema, 1989). Individuals develop different performance expectations of its members based on cultural characteristics, even if those characteristics have nothing to do with the group's task. Individuals with low- and high status develop a positive bias toward people who are believed to bring more resources into a group (Ridgeway et al., 1998). However, there are ways in which low-status members such as women can improve their chances of gaining status in groups by, for instance, legitimizing the position of women as leaders in a group setting (Lucas, 2003) or having female leaders emphasize how their work contributes to the good of the group (Ridgeway, 1982). Findings from the status characteristics approach help to elaborate the ways that larger social forces operate in groups and how group interactions help to maintain traditional stereotypes about people with different statuses in society.

Sociobiology

Sociobiology is the study of the relative impact of social and biological factors on individuals' thoughts, feelings, and behaviors. Sociologists also emphasize the ways that people construct the meaning of their biological world, giving more or less importance to certain traits or attributes (e.g., physical attraction) or/and how individuals come to define something as biologically inherited or not (e.g., sexuality).

Twin research is one major way that sociologists examine the relative impacts of genetic inheritance over social interaction in the production of social life. By comparing monozygotic (identical) twins who share 100% of their DNA with dizygotic (fraternal) twins, siblings, and nonrelated children, researchers can assess the degree to which nature impacts social psychological outcomes over social conditions because nonrelated family members share the same social conditions but not DNA, while identical twins share all of the same genetic traits. Using this technique, Nielson (2006) found shared genetic inheritance was more important for the transmission of verbal IQ and grade point average than shared family environments. However, social influences explained a significant amount of these outcomes and Horwitz et al. (2003) caution that twin studies can overstate genetic influences because identical twins both share a greater genetic as well as environmental background compared to both dizygotic and other siblings.

Gene–environment interactions represent another major way that sociologists and other social scientists assess the relative impacts of biology and social conditions on social psychological outcomes. Under this model, specific genes are thought to impact environmental outcomes and vice versa. Hence, while genes are thought to contribute to individuals' decision-making processes, environmental conditions interact with those genes and genes can also be impacted by social conditions. For instance, Guo et al. (2008) found that high levels of alcohol use among one's peers tend to bring about higher levels of genetic contribution to alcohol use. In other words, environmental conditions appeared to trigger the relationship between genetic disposition and alcohol use. In another study, genetic disposition explained variation in delinquency but these effects were mediated through levels of social control from family, schools, and peers (DeLisi et al., 2008).

Sociologists regularly test assumptions about the biological causes of social behaviors. Research generally shows differences in things like IQ vary among social groups and are thought to be inherited (Herrnstein and Murray, 1994). Girls, specifically, report lower math ability and are less likely to pursue careers in mathematics and the sciences. While some analysts believe that differences in math ability are genetically inherited, scholars in the group processes perspective have been able to influence both IQ scores and career aspirations simply by manipulating perceptions of abilities of subjects in experimental settings (see Correll, 2004; Lovaglia et al., 1998; Ridgeway et al., 2009; Rosenthal and Jacobson, 1968). While some emotional expressions such as fear and anger appear to have similar meaning across cultures, the conditions that arouse these and other emotions, their expressions and labels vary from place to place, suggesting both biological and social causes (Ekman, 2007; Kemper, 1987; Thoits, 1989). Sociological research also challenges the stereotypes of gender differences in emotional expression (Simon and Nath, 2004). Finally, while medical diagnoses may be associated with biological causes, their meanings and treatment change over time based on social influences such as the authority of medical professions, interest groups, and other groups like pharmaceutical companies who have a stake in the labeling and treatment of patients (Conrad, 2005).

Conclusions

Sociological social psychology emphasizes the ways that society shapes social psychological processes. From this perspective, society is a network of interaction among people (Blumer, 1969). Society is shaped by individuals' social interaction thereby creating a dialectic in which individuals are shaped by society. The symbolic interaction, social structure and personality, and group processes perspectives utilize this framework to examine the intersection of the individual and society. Even biological outcomes can be impacted by these social processes.

Abstract

This article presents some of the issues attached to the research methods used in Social Psychology. First it introduces the different methods used in social psychological research (quantitative and qualitative) and discusses the basic epistemological assumptions that lie on the basis of each of them. Then it presents methods of generating/collecting data and techniques of quantitative and qualitative data analysis. Finally, it briefly discusses issues related to validity and reliability of qualitative and quantitative research in Social Psychology and highlights the importance of addressing social psychological questions through the use and analysis of empirical data.

Over the years researchers identifying their research as social psychological have used a variety of methods to answer their research questions. These can be categorized as quantitative (experimental and nonexperimental) or qualitative (analytic techniques employed to analyze data generated through interviews and focus groups discussions, but also naturally occurring data). Although the division between qualitative and quantitative research methods coincides with debates about Social Psychology as a discipline, here we take the stance to present the different methods in a single article, highlighting their epistemological differences but assuming that both types of methods characterize the discipline. We will briefly present the methods, their epistemological foundations, and the questions they imply, and then we will present some techniques of generating and analyzing data. The article starts alphabetically from qualitative research methods and then moves to quantitative research.

Qualitative Research Methods in Social Psychology

The term 'qualitative research methods' is employed (1) to describe ways of generating and analyzing data which are not reducible to numbers (more often than not, texts and less frequently visual material) and (2) to refer to a broader framework within which certain epistemological and ontological assumptions prevail (Clarke and Braun, 2013). While in some cases qualitative research is used as a forerunner of quantitative research (analysis of interviews or focus group discussions often constitutes a first step toward the construction of a survey questionnaire) or as part of a mixed-methods research design, in other cases the choice of qualitative methods reflects a specific way of understanding social psychological phenomena and social psychological knowledge (*see* Social Constructionism).

The expansion of qualitative methods is, more often than not, related to the 'crisis' debates of the 1970s that included a critique on social psychological method(s) (*see* Critical Psychology). However, it is not until the late 1980s and 1990s that qualitative methods gained a foothold in Social Psychology, as a consequence of the development of post-modernist and post-structuralist perspectives and the so-called 'discursive turn' (*see* Social Psychological Theory, History of). Some basic principles of qualitative research – although different approaches do not share the same level of commitment to them – include the following: (1) a focus on meaning and interpretation, (2) a preference for inductive, theory-generating research, (3) sensitivity to the situated, context-specific nature of meaning, and (4) recognition that researchers' perspectives and subjectivities are intrinsically involved into the research process (something that in quantitative research is termed bias and it is treated as an unwelcome weakness). These qualitative methods are also used in other social science disciplines, especially in anthropology, cultural psychology, and cross-cultural psychology.

Methods of Collecting/Generating Qualitative Data

Interviews

Interviewing constitutes probably the most common and popular qualitative data collection technique. It normally involves a 'dialogue' with the researcher setting the agenda and asking questions and the interviewee being cast in the role of respondent. Nevertheless, interviews as a specific type of dialogue can be more or less structured. In structured interviews – rarely used in qualitative research – both the wording and the order of the questions are the same from one interview to another. In unstructured interviews, on the other hand, a free-flowing conversational style is adopted and respondents are encouraged to raise issues not originally included in the interview schedule. Biographical interviews which aim at the elicitation of research participants' personal stories with minimum researcher prompting constitute a paradigmatic example of unstructured interviews. Finally, in semistructured interviews, which are most commonly used in qualitative research, the researcher sets the agenda on the basis of their own interests and topics, but allows room for the participants' more spontaneous descriptions and narratives. Other distinctions are between one-to-one versus group interviewing, face-to-face versus

telephone interviewing or interviewing through the Internet (Madill and Gough, 2008).

Focus Groups

Focus groups constitute researcher/moderator-led group discussions designed to extract opinions about a topic. They have been originally developed in market research, but they gradually became a popular data generating method in academic research and especially in research projects that involve previously unexamined topics (Krueger and Casey, 2000). Focus groups provide a context which allows for the development of argumentation and counterargumentation and for the exploration of the interactional mechanisms involved in sense making. They are also considered a method appropriate to study groups whose voices are often marginalized within the larger society.

Interviews and focus group discussions are usually audio-recorded – researchers who intend to take into account nonverbal aspects of communication in their analyses tend to video record their interviews – and then transcribed. Transcription is a laborious task and demands prolonged practice. It is also an interpretative process that requires sensitivity on the part of the researcher to the nuances of oral speech and its differences to written language.

Naturally Occurring Data

This category includes a range of texts and interactions produced in the course of everyday life. The researcher is actually involved only in the sampling of the material. The virtues of using naturally occurring data are usually highlighted through their comparison to the artificiality of research interviews. According to critiques (Potter and Hepburn, 2005) an interview is carried out to serve the researcher's ends and agendas, which are external to the conversation itself and (potentially) irrelevant to the participants' interests. Naturally occurring data include archival documents (ranging from television programs and Internet materials to official/institutional archival data such as health records), naturally occurring conversations (therapy sessions, telephone calls recorded in the normal course by service providers) and – less frequently – visual material such as photographs or murals.

Observation

It has formed the basis for much qualitative research. In common with the category of naturally occurring data it is appropriate for the study of behavior that cannot be produced in an artificial environment for practical or even ethical reasons. Among its advantages is that it allows researchers to understand processes, to understand social life as involving interrelated series of events. Different types of observation are constructed on the basis of criteria such as the extent to which researchers intervene in the phenomenon of study or interact with research participants (Silverman, 1993). Structured observation refers to a situation where the researcher creates the context where a behavior can occur. Systematic observation involves a trained researcher who observes and codes the phenomena of study according to a prearranged set of criteria. Participant observation refers to a form of systematic observation whereby the observer interacts with the people being observed. Ethnography is a type of observational method used initially by cultural anthropologists and more recently by social psychologists to study and understand a group or culture. Ethnographic observation involves participation in a cultural-social context over a lengthy period of time.

Structured Methods of Data Collection

Sometimes qualitative research in Social Psychology may use more structured methods of data collection (also often used in quantitative research) such as open-ended questionnaires, Q-methodology and repertory grids, protocols (verbal or written records of observations or experience, obtained in response to a standardized question) designed, or vignettes (a scenario is provided for participants to consider and answer questions).

Methods of Qualitative Data Analysis

Qualitative Content Analysis

Content analysis is basically a quantitative method that involves establishing categories and counting the number of instances that these categories appear in a corpus of data. However, the method is also employed in qualitative research in which systematic classification procedures are used to categorize qualitative textual data into clusters of meaning (categories or themes). Qualitative content analysis is more interpretative in comparison with its quantitative counterpart and it is interested not only in the 'manifest' meaning of words or phrases but also in its 'latent' underlying meaning (Mayring, 2000). Coding systems consist of rules for assigning specified units into categories. Normally, categories are intended to be unidimensional, exhaustive, and mutually exclusive, but this is not always the case in qualitative content analysis (a piece of text may be relevant to more than one category). The implementation of content analysis has been drastically affected by the development of software packages, such as NVivo, Atlas ti, Dedoose.com, and the recently developed QCAmap. These tools can assist the researcher in handling and organizing large quantities of data but they cannot diminish the need for intellectual effort on the part of the analyst. Content analysis can be applied to a whole variety of data (including nonverbal data, such as pictures, drawings, gestures, etc.) and in relation to a variety of research questions. The fragmentation of texts and the decontextualization of data (as instances, pieces of text or answers are separated from their contexts) constitute potential disadvantages of the method.

Grounded Theory

A methodological approach was first developed by the sociologists Glaser and Strauss (1967). Glaser and Strauss criticized research derived from highly abstract theories that it fails to come up with explanations that are of relevance to those being studied. Hence, they developed a method aiming to generate a local, contextual theory, grounded on data. Therefore, the term grounded theory refers both to a method of inquiry, as well as to the theory produced by the implementation of method. The method includes an initial coding phase in which researchers work systematically through the data corpus generating codes (analytic labels) to describe both low-level concepts, as well as, more abstract categories. Throughout the process, they write memos elaborating their codes, identifying analytic gaps, and comparing analytic categories. Constant comparison and theoretical sampling constitute principal

analytic tasks of the method. Constant comparison involves continually comparing elements (analytic categories and theoretical presuppositions), while theoretical sampling involves the active sampling of new data that inform theoretical categories as the analysis proceeds. The emphasis of the original grounded theory method on *discovering* theory from data with its empiricist connotations was criticized by scholars who emphasized the constitutive nature of the analysis and developed more social constructionist revisions of the method (Charmaz, 2006).

Thematic Analysis

There is no agreement if it really constitutes a specific method in its own right. It is often rather unclear which its differences with qualitative content analysis are, and its use has been fairly inconsistent (see, however, Braun and Clarke, 2006; for a systematic introduction to the method). Thematic analysis also involves (usually inductive) coding of qualitative data into clusters of similar entities, or conceptual categories and the identification of consistent patterns and relationships between themes, so as to come up with a theoretical explanation of the phenomenon under study.

Interpretative Phenomenological Analysis

Its central focus is on the understanding of subjective experience and on the meaning attached by participants themselves to their lived experience. Unstructured or semistructured interview data are considered to be the ideal path to the participants' subjectivity. In terms of initial coding and the process of identification of emergent themes within the corpus of data Interpretative Phenomenological Analysis is also very close to some versions of thematic analysis and grounded theory (Smith et al., 2009).

Narrative Analysis

Narrative analysis refers to a cluster of analytic methods for interpreting texts or visual data that have a storied form. A common assumption of narrative methods is that people tell stories to help organize and make sense of their lives and their storied accounts are functional, and purposeful. Different approaches to narrative analysis are categorized on the basis of whether they focus on the narrative content or structure, with the thematic version interrogating what a story is about, while the structural version asks how a story is composed to achieve particular communicative aims. To this basic typology, according to Kohler Riessman (2008), one could also add the dialogic/performance narrative analysis, which focusses on the context and view of narratives as being multivoiced and coconstructed and the visual which links words and images in a coherent narrative.

Discursive Methods (Discourse Analysis/Discursive Psychology)

There are a variety of related – but also fundamentally distinct – methods grouped under the rubric 'discursive' or, most commonly, 'discourse analysis.' What is common between different methods is the recognition of the vital role of discourse in social life and an approach to language as social practice, instead of a pathway to inner cognitive entities (*see* Social Constructionism). Nevertheless there is little consensus between approaches on the ancestors and the epistemological basis of the analysis, on the analytic objectives, and on the conceptualization of the very notion of *discourse*. Potter and Wetherell (1987) – influenced by speech act theory, ethnomethodology, semiology, and post-structuralism – used the term 'discourse' to refer to virtually any language use and considered interpretative repertoires (recurrently used units of content, situated in certain – usually interview – contexts and oriented toward different interactional but also macro-social functions) as the units of analysis. On the other hand, scholars influenced by Foucault's work defined discourse as "a system of statements which constructs an object" (Parker, 1990: 191) and tended to fracture texts into discrete discourses which subjectify speakers and reproduce power relations.

The early 1990s witnessed also the emergence of discursive psychology (Edwards and Potter, 1992) which is informed by conversation analysis (CA) and prioritizes the use of naturalistic data. Its focus is on the role that descriptions of the world (including descriptions of psychological states) play in the management of speakers' accountability and in the formation of action. In the years to come, discursive psychologists became more deeply engaged with CA, working with conversational corpora from everyday and institutional settings, transcribed by the use of conventions developed by Gail Jefferson. Between the boundary lines among this strand of work, which affiliates with ethnomethodological traditions, and analytic perspectives which follow Foucaultian lines, other scholars proclaimed (Wetherell, 1998) an eclectic engagement with both CA and post-structuralism (and therefore engagement with both the interactional as well as the broader ideological functions of language use) as the most productive starting point for discursive methods in Social Psychology. This approach is known as critical discursive psychology.

Conversation Analysis

CA refers to a specific approach to the analysis of interaction that emerged in the 1960s in the work of Harvey Sacks (Sacks, 1995). CA is interested to understand social order by focusing analytically on the sequence of talk in interaction and on the ways participants organize mundane conversation. The recent engagement of discursive psychologists with CA blurs the boundaries between the two as analytic methods in Social Psychology.

Rhetorical Analysis

Interest in rhetoric in Social Psychology also arose as part of the discursive turn. Key text through which rhetoric was introduced in social psychological analyses constitutes Billig's (1987) '*Arguing and Thinking*.' Given his preference for scholarship, instead of methodology, Billig did not intend to introduce an analytic method in the narrow sense of the term. The text did not adhere to any specific methodology and neither included any methodological guidelines. Nevertheless, it served to deepen and enrich the understanding of how to approach analytically context and content in qualitative research, by advocating the need to consider the rhetorical relation between topics (as units of analysis). According to Billig (1987), in order to capture the meaning of any commonplace assumption, we should put it in

its argumentative context and examine it in relation to the commonplace that it aims to downgrade. Rhetorical analysis is also interested in relating meaning, or rather disputes over meaning, to the broader historical ideological context.

Validity and Reliability in Qualitative Research

There is considerable debate regarding the extent to which validity and reliability criteria – which have been defined in quantitative research and are imbued with its assumptions – are appropriate to evaluate the *quality* of qualitative research. According to some authors, qualitative researchers can and should incorporate criteria and techniques that deal with issues of reliability and validity and adjust them in their own epistemological framework. Silverman (1993), for example, maintained that triangulation techniques (of researchers or/and of data sources) can vitally contribute to the quality of research inquiry and can be compatible with the constructionist epistemology that underlies many qualitative research methods, if they are considered as highlighting the situated use of different accounts, instead of being treated as a means to prioritize one account vis-à-vis others.

Other researchers, however, prefer to replace validity and reliability with terms and criteria more compatible to the interpretivist background of qualitative research. Potter and Wetherell (1987) suggested *coherence* of the analytic framework (the potential of the analytic framework to give coherence in a body of data by accounting both for regularity and variability within it), *fruitfulness* (the extent to which the analytic scheme generates novel explanations), *new problems* (the identification of contradictions and exceptions from the explanatory scheme that necessitates new analytic questions and answers), and *participants' own orientation* (the way in which participants themselves see what analysts may consider as consistent, contradictory, etc.) as validation criteria of discourse analysis. Interest in understanding the phenomena from the participant's view as a validation criterion of the quality of the analysis has been developed also in other methods. Grounded theorists, for example, also maintained that the extent to which results may be recognizable and may be of relevance to those studied constitutes a vital criterion of research quality. Finally, a usually mentioned criterion of qualitative analysis's validation concerns the extent to which researchers' reflexivity is built into the analytic process.

Quantitative Research Methods in Social Psychology

Quantitative research is one that relies primarily on information of quantitative (i.e., numerical) nature. It conceptualizes reality in terms of variables, which measures and explores by applying statistical techniques in order to study relationships between them (Punch, 2014). Quantitative research is considered a 'top-down' approach in the sense that specific hypotheses deriving from a theory are tested through data analysis. Following the epistemological tradition of determinism, according to which events are accounted for by one or more causes, it assumes that behavior is explainable. Therefore, quantitative researchers try to make probabilistic predictions and generalizations by identifying cause-and-effect relationships. Supporting the ontological claim of objectivity, they strive to remain neutral and study the phenomena of interest 'from a distance,' which is expected to ensure validity of measurement and replicability of their findings (O'Dwyer and Bernauer, 2014).

As an empirical science, Social Psychology attempts to answer questions of quantitative nature about human behavior by testing hypotheses both in the laboratory and in the field. This corresponds to the distinction between experimental versus nonexperimental/correlational research designs. Although sometimes presented as essentially different or even incompatible, the difference between the two methods may be preferably understood in terms of the level of control exerted over the variables under study (Tajfel and Fraser, 1978).

Methods of Collecting/Generating Quantitative Data

Experimental

Although social psychologists employ a variety of methods to explore their research questions, the experimental paradigm has largely dominated the field, being characterized as the workhorse of Social Psychology (Wilson et al., 2010). An experiment involves measuring the effect of different conditions, intentionally manipulated by the researcher, on a behavioral outcome of interest. The former constitute the levels of an independent variable, while the latter is referred to as dependent variable. Not surprisingly, experiments are usually conducted in laboratory settings, which offer maximum control over the independent variable and minimal intrusion of third factors, thus allowing for testing hypotheses regarding causal effects.

The main advantage of an experimental design relies exactly on the ability to ensure all three preconditions for establishing causality, namely temporal precedence, covariation of the cause and effect, and exclusion of alternative plausible explanations (Trochim and Donnelly, 2007). This is not a simple task though: researchers must be careful to randomly assign individuals across the experimental conditions, to disentangle confounded variables, to avoid extreme conditions (that would lead to floor or ceiling effects), to exclude demand characteristics of experimental settings (that would lead to biased responses of participants), and to favor experimental versus mundane realism, i.e., 'true' psychological impact versus intrusive effect of everyday encounters (Hogg and Vaughan, 2010).

On the other hand, having enough control over the experimental conditions usually implies that the results cannot be generalized to everyday life, which means that there is a trade-off between internal and external validity. This can be dealt with by conducting field experiments, where experimental conditions are manipulated in real-life settings. However, some researchers warn that field experiments do not actually increase external validity as findings may or may not generalize to different real-life settings (Dipboye and Flanagan, 1979). Beyond the issue of validity, it may not be ethically acceptable or even possible for researchers to perform controlled experiments. In such occasions, nonexperimental methods are employed in order to collect quantitative data.

Nonexperimental

Quantitative nonexperimental methods refer to correlational studies, which focus on the naturally occurring associations among two or more factors. The use of advanced statistical software gave a boost in the number of variables, as well as in the complexity of the relationships, that can be examined simultaneously in a correlational study (see the next section). However, one should always bear in mind that any correlation-based technique, no matter how sophisticated, cannot determine causal effects. To compensate for reduced internal validity, the enhanced external validity associated with nonexperimental designs contributes to the development of social psychological theory by providing robustness (i.e., replicability of findings), representativeness (i.e., real-world processes), and social relevance (Brewer, 2000).

The most common method of data collection in a nonexperimental design is a survey study. Related developments – most notably, the widespread use of information technology – have broadened the range of choice of researchers to include techniques such as Internet research, diary methods, ambulatory assessment, and trace measures (see Reis and Gosling, 2010). These are briefly introduced below:

Survey

In quantitative studies, survey data are usually collected through the administration of self-report scales or questionnaires using the paper-and-pencil method. Surveys can obtain a large amount of information from a large number of participants in a short period of time. The psychometric properties (i.e., reliability, validity) of the measures, random sampling (in order to maximize representativeness of the general population), respecting the code of ethics (e.g., informed consent, anonymity, and confidentiality of responses), and – of course – implementing the appropriate statistical techniques are some key-issues to a successful survey. The numerous types of attitudes and values research are typical examples of survey studies.

Diary Methods

Diary studies adopt a within-subject approach by collecting repeated measures from the same number of participants at different time points. They are designed to capture life in real-world settings. Their use became more popular along with the development of multilevel statistical software, such as Hierarchical Linear Model (HLM) (see below). Topics of interest in diary studies are, among others, personality traits, emotions, social interaction, marital and family interaction, stress, and subjective well-being.

Ambulatory Assessment

This refers to the use of mechanical or electronic devices that record information about an individual's activity or state in natural, everyday settings. Some applications include ambulatory cardiovascular monitoring, electronic recording of the acoustic environment, activity monitoring, and location mapping (Reis and Gosling, 2010).

Internet Research

Initiated in the 1990s as a convenient means to increase the number of participants, complementary to the traditional paper-and-pencil method, the Internet soon became a new, dynamic, rapidly growing field of research. Of special attention are phenomena unique to the virtual environment, such as personal Web pages, forums, and the various forms of social networking (e.g., Facebook, Twitter, etc.). At the same time, a number of concerns have been raised against Internet studies, focusing on issues such as the characteristics of participants, the potentially fake identity of responders, or the reduced replicability and generalizability of findings compared to other methods. Although some of these issues have been addressed (e.g., Gosling et al., 2004), the physical distance between researcher and participant remains a major drawback and, at the same time, a distinctive advantage of Internet research.

Trace Measures

These studies are based on the fact that certain social behaviors, attitudes, cognitions, and emotions leave physical traces. Although Reis and Gosling (2010) accept that the environmental evidence of social psychological behaviors is largely untapped by researchers, they stress the potential value of trace measures, as the manifestations of an individual's thoughts, emotions, and actions go beyond physical environments.

Methods of Quantitative Data Analysis

Statistical methods are important tools for social psychologists in order to explore their research questions or examine specific hypotheses. These tasks typically correspond to the distinction between exploratory and confirmatory data analysis introduced by Tukey (1980), who wisely warned that confusing the two types of analysis can lead to systematic bias due to issues inherent in testing hypotheses suggested by the data. However, as Judd and Kenny (2010) point out, most data analysis in Social Psychology is essentially confirmatory, in the sense that researchers are guided by overtly or implicitly causal theories they seek to confirm. These models often include both direct and indirect effects; they may also expand to incorporate different levels of explanation, such as the intrapersonal, the interpersonal, the positional, and the ideological (Doise, 1986). In order to understand such complex relations in their data, researchers are supported by recent developments in advanced statistical techniques, such as structural equation modeling (SEM) and multilevel modeling (MLM), usually implemented by powerful software. In the following, these developments in quantitative data analysis will be briefly presented with respect to two issues of core importance in social psychological research, namely causal modeling and levels of analysis.

Causal Modeling

A causal model represents the relations between a given set of variables. It can take the form of a statistical equation and it is usually graphically depicted. SEM is in fact an extension of regression analysis for testing and estimating causal relations, which also allows for inclusion of latent constructs represented by a number of measured variables. The existing, constantly evolving SEM statistical software, such as AMOS, EQS, LISREL, and Mplus, providing powerful controls in what concerns model testing, modeling error, treatment of missing data, and testing invariance across multiple groups.

Causal models guide social psychological research by setting the ground for building and testing specific hypotheses.

Statistical handling of data collected within this framework can be quite complicated as it may include multiple variables and their relations are examined simultaneously in a number of combinations, which goes far beyond the traditional analysis of variance (ANOVA) and multiple regression techniques. Even in simple experimental designs as well as in nonexperimental correlational studies, research hypotheses may refer to indirect effects, which involve the inclusion of third variables explaining or modifying the relations between an independent factor and an outcome. Baron and Kenny's (1986) seminal work discussed in depth the conceptual, strategic, and statistical considerations of distinguishing between two types of third factors affecting a causal relation, i.e., the mediator and moderator variables.

Mediation

A simple mediation model suggests that the observed relation between an independent variable and an outcome can be explained by the effect of a third factor, known as mediator. According to Baron and Kenny (1986), three prerequisites are necessary in order to establish mediation: (1) the independent variable should be a significant predictor of the dependent variable; (2) similarly, the mediator should have a significant effect on the dependent variable; and (3) the mediator should be a significant predictor of the dependent variable while controlling for the effect of the independent variable. A relation is *fully mediated* when the direct path from the independent variable to the outcome becomes nonsignificant after accounting for the effect of the mediator. *Partial mediation* occurs when the mediator accounts for some, but not all, of the relation between the independent variable and the outcome. The amount of mediation is called the *indirect effect*.

A simple, common technique to identify mediation is Sobel's test (1982), which compares the difference in the relation between the independent variable and the outcome before and after inclusion of the mediator in the regression equation. More recently, Preacher and Hayes's (2008) nonparametric bootstrap method has become increasingly popular, which is recommended for small samples as it does not violate assumptions of normality. SEM programs or especially written statistical software macros can be applied in order to test for complex cases of mediation, such as multiple independent factors or outcomes, multiple mediators or latent variables used as mediators (see, for example, the Web pages of Andrew Hayes, http://www.afhayes.com/, and Kristopher Preacher, http://www.quantpsy.org/men.htm).

Beyond statistical complexity, it should be underlined that mediation is primarily a conceptual issue, i.e., the conclusions from a mediation analysis are valid only if the causal assumptions hold true (Judd and Kenny, 2010). Therefore, researchers should make sure that reverse causal effects (e.g., the mediator being caused by the outcome) or confounding variables (i.e., factors causing both the mediator and the dependent variable) are not present. Also, the mediator should be reliably measured in order to minimize bias.

Moderation

If mediation analysis attempts to explain 'how' or 'why' an effect occurs, moderation refers to the question of 'when' this effect holds, i.e., if the strength and/or direction of the relation between two variables is affected by the presence of a third variable, known as the moderator. Moderation suggests that the characteristics of the relation between an independent factor and an outcome vary at different levels of a moderator, while mediation suggests that the relation between an independent factor and an outcome is fully or partially explained by a mediator. Statistically speaking, moderation represents an interaction or a product in factorial ANOVA or in multiple regression, depending on whether the moderator is qualitatively or quantitatively measured, respectively (see Hayes and Matthes, 2009; for computational procedures of calculating interaction terms). From a conceptual point of view, hypotheses involving moderation address the question of invariance of causal relations between an independent variable and an outcome across different units, such as persons, situations, or cultures. In fact, any causal assumption implies some degree of invariance across persons. Judd and Kenny (2010) remind us of other sources of invariance including time points, situations, experimental stimuli (e.g., evaluative priming procedures), specific statistical techniques (e.g., meta-analysis, logistic regression), and cross-cultural comparisons. Invariance indicates the replicability of our findings and the limitations in generalizing our conclusions. In methodological terms, moderation analysis provides evidence of external validity as it examines to what extent a causal effect is considered universal.

Statistical handling of data in moderation analyses goes beyond simple identification of a significant partial effect of a product predictor in a linear model. Common problems include, among others, multicollinearity and power. Multicollinearity may yield coefficients with higher standard errors since the interaction term of two continuous variables (i.e., the moderator) inevitably correlates highly with the two main effects used to calculate it. Low statistical power indicates that replication of a significant moderation effect is difficult to achieve, especially with continuously measured independent variables, and calls for the use of large sample sizes.

In addition to the assumptions for applying specific statistical procedures, Judd and Kenny (2010) elaborate on some more perplexing issues of moderation testing. Not surprisingly, their discussion raises the problem of causality from a theoretical perspective once again. They show that the direction of causality between A and B (i.e., the decision on which variable will be treated as independent or outcome) matters a great deal in moderation testing, especially when the homogeneity of variance assumption is violated, so that A or B vary differently at high and low levels of the moderator. In such statistically ambiguous situations, a solid causal theory is necessary to indicate how moderation is assessed.

Mediated Moderation and Moderated Mediation

It is not rare that both mediator and moderator variables are integrated in a causal model. In these cases different hypotheses can be drawn, which are extensions of the simple mediation and moderation frameworks and they are defined accordingly. In *moderated mediation*, the mediating effect of a variable in the relation between an independent factor and an outcome varies across different levels of a moderator (Preacher et al., 2007). In *mediated moderation*, the effect of a variable moderating the relation between an independent factor and an outcome is accounted by the mediating process of another variable (Muller

et al., 2005). Therefore, moderated mediation and mediated moderation do not necessarily imply the existence of two different data sets, but rather two different causal models guiding research hypotheses, which can be based on the same data set.

Although mediation and moderation analyses are quite common in social psychological research literature, mediated moderation and moderated mediation hypotheses are not frequently examined, which would be particularly informative in extending the theoretical models used. This may be due to the statistical complexity of such questions, as computational routines to conduct these analyses are only recently being developed. Fairchild and MacKinnon (2009) provide illustrated examples of the equations required to simultaneously estimate mediation and moderation effects; they also underline the contribution of these techniques in applied settings, where the questions of 'how' and 'for whom' an intervention program is effective become crucial.

Modern SEM computer programs, with their user-friendly graphical interface and huge estimating capabilities, facilitate the conceptual and statistical handling of mediation and moderation analyses, provided that researchers are respectful with regard to consideration of assumptions (see Bentler and Chou, 1987; for an excellent overview). Testing of alternative models on the grounds of goodness-of-fit indices is particularly enlightening in terms of theory building. For example, longitudinal designs may benefit from examining four competing hypotheses referring to stability, causality, reversed causality, and reciprocal causality, respectively. Yet, it should be reminded that SEM is a confirmatory – as opposed to exploratory – technique, which means that it can be used to compare multiple theories that are specified a priori.

Levels of Analysis

Although many social psychological theories focus on individual processes, they are inherently placed at the interface between personal and group phenomena; therefore, hypotheses drawn on these theories may include multiple levels of analysis. The term *MLM* – which is a shortcut for *multilevel random coefficient modeling*, also known as *hierarchical linear modeling*, among others – is used to describe hierarchically structured data, i.e., observations at one level which are nested within observations at another level. For example, employees (L1) are nested within departments (L2) and organizations (L3); students (L1) are enrolled to different classes (L2) and schools (L3); in cross-cultural studies, individuals (L1) come from different countries/cultures (L2); in diary studies, emotions at different events or time intervals (L1) are nested within persons (L2). As Kreft and de Leeuw (1998) put it, once we realize hierarchies exist, we recognize them everywhere!

In statistical terms, the key question is whether observations are independent or not. In hierarchically structured data observations at L1 are not independent, which violates a fundamental assumption of traditional ordinary least squares (OLS) techniques, such as ANOVA and regression. Single-level analyses that ignore the hierarchical structure of data may provide misleading results because relations at different levels of analyses are in fact independent. Van de Vijver and Poortinga (2002) provide a taxonomy of multilevel fallacies occurring when different patterns of relations across levels are ignored. Additionally, in social psychological research inferences are made for a unit of analysis by studying random samples. MLM takes into account simultaneously the sampling error at different levels, which is not the case with traditional OLS. Therefore, MLM produces more accurate estimates than OLS because it considers the reliability of scores and the differences in sample sizes. These advantages are pronounced when hypotheses of interest concern within-unit relations, and when the data structure is irregular, for example, due to missing data (Nezlek, 2008).

MLM is appropriate when research questions involve more proximal (L1) and more distal (L2, L3…) factors influencing individual behavior, or simply when the data are hierarchically structured. Two issues of relevance need to be considered here: (1) the nature of the variables used; and (2) the nature of the relations between levels. Variables in a multilevel model may be intrinsic or derived (either aggregated or disaggregated; see Van de Vijver and Poortinga, 2002). The latter case raises concerns about equivalence, i.e., to what extent a construct measured in different groups has the same underlying structure. Structural equivalence is a precondition in order to perform group mean comparisons. It can be examined by calculating a congruence coefficient (e.g., Tucker's phi) through exploratory multilevel factor analysis procedures, or by applying multilevel confirmatory factor analysis with the use of SEM programs. Another question of interest is to what extent the same pattern of predictor–outcome relations holds across L2 units, e.g., across groups, cultures, or time points. This is typically referred to as a cross-level interaction. Conceptually similar to moderation, it is substantive for social psychologists who seek to explore the interplay between different levels of explanation (Doise, 1986) and can be examined through specialized statistical software (HLM).

Some Additional Comments

Error

Dealing with error in quantitative data analysis is almost as important as model testing. Although relevant assumptions (such as lack of measurement error and homogeneity of error variance) are embedded in OLS analyses, researchers sometimes tend to overlook them. Violation of these assumptions may lead to unfortunate conditions, such as measurement bias, attenuation of measures of association, reduced power in testing interactive effects, and underestimation of mediation effects, among others (Baron and Kenny, 1986). Therefore, obtaining reliable measures, identifying outliers, testing for nonnormality, and treating sources of error at different levels are necessary steps to be taken prior to any analysis involving specific hypothesis testing.

Variable Coding

In a regression equation, the parameter estimate of a predictor indicates the effect of the predictor on the criterion variable when all other predictors equal zero. Therefore, all simple effects are meaningless if zero is not a meaningful value for the predictors included in a regression model. This straightforward statement is not always fully understood by researchers, thus leading to a series of misinterpretations. When a categorical predictor is coded as 1 versus 2, then the slope of a continuous independent variable points to a nonexistent level of the

categorical predictor. An easy solution for this problem is to use a coding of 0 versus 1. Even in that case, the slope of a continuous independent variable is not a 'main effect,' as presented by many, but rather the simple effect of that independent variable when the categorical predictor equals zero.

In the same underlying rationale, when calculating the product for a regression interaction term it is advised that the two component variables are centered prior to computing their product, so that zero is an interpretable value for both predictors (Aiken and West, 1991). Of course the above is not necessary if zero is already a meaningful value, like for example, in Likert scales coded from −3 to +3, instead of 1–7. In multilevel models, variable centering can affect significance tests, but most dramatically it changes intercepts and error terms (Kreft and de Leeuw, 1998). HLM software provides two centering options (in addition to the uncentered solution), namely grand mean centering and group mean centering, depending on whether the slopes represent deviations from the overall mean or from each group's mean, respectively. With grand mean centering, estimates of slopes include between group differences in means of predictors, which are not included in group mean centering. At L2 (in two-level models), it is preferred to grand mean center, as this helps interpreting the intercept. At L1, group mean centering is closest to conducting within group regression analysis.

Missing Data

Missing data are quite underestimated by researchers. In any paper describing a quantitative statistical method there is a section devoted in how to treat missing values, often skipped by some readers. However, the presence of missing observations may have important implications, from restricting the generalizability of the findings to practically preventing an analysis from running at all. A typology describing missing data in terms of their underlying cause is owed to Rubin (1987): missing completely at random, missing at random, and missing not at random. The strategies for handling missing data include case (listwise) deletion, imputation by using a substitute value (such as the group mean or a multiple regression estimate), and multiple imputation (a method that estimates the sampling variance due to imputation). These strategies differ in terms of sophistication, which in turn attempts to compensate for their disadvantages. Therefore, they should be studied carefully before being applied in a given data set through modern powerful statistical software.

Judd and Kenny (2010) urge social psychologists to be more creative in how they deal with missing data, which they believe can lead to new insights about their research designs. Overall, perceiving statistical analyses as a challenging opportunity to discover rather than a routine of imposed restrictions will help researchers get the most out of their data and improve their theories.

Conclusion

In this article, we presented the methods used by social psychologists in order to set and address research questions, to generate and analyze empirical data, and to contribute to social psychological knowledge. We devoted space both to qualitative and quantitative research and we attempted to highlight not only the differences between them but also the diversity within each research tradition. Of course many supporters of each tradition would disagree about the extent to which a pluralistic stance toward method is preferable or even acceptable, although a *mixed-methods* research approach combining the quantitative and qualitative typologies is gaining ground in recent years (e.g., Bryman, 2006). In any case, it is hard to disagree that the diverse ways of generating and analyzing empirical data and the importance attributed to this process has given Social Psychology as a discipline a distinctive identity among the social sciences.

Social Question: Impact on Social Thought

Giovanna Procacci, University of Milan, Milan, Italy

Abstract

Social question meant the rationality of poverty problems that took place with the rise of modern liberal societies. Within a social order based on the egalitarian premises emancipating individual rights and labor, poverty challenged both legal and economic emancipation, as well as their ability to organize a stable social order. Poverty therefore became a public concern about the dangers that inequalities produced by modernity, represented for the collective body. Searching for an autonomous definition of its scientific methods and hypotheses, at a distance from legal and economic sciences, early social science found its first field in the analysis of the social question. If social science was to analyze the organized group and its conditions, then poverty was both disruptive and crucial, because it could only be treated within a framework of obligations, more central to a collective, rather than a mere set of individual rights. Origins within poverty analysis deeply marked sociology foundation concepts making them organic, moral, and animated by a will to reform that gave the structure of a political program to scientific sociology. The social question therefore tied sociology to the development of an administrative state, reviving the 'intermediary groups' that liberalism had eliminated from the social body.

A modern social science not only originates within an intellectual project of widening rational knowledge, but also as a means to govern what Simmel (1908) called 'the material of social processes.' The making of what Comte (1848/1957) described as 'the preponderance of a social point of view' implied that there were problems that no established scientific approach could successfully address. Even more, the individualistic premises of modern legal and economic sciences themselves opened new problems from the vantagepoint of social organization. If the major trend of modernity has been toward the legal emancipation of the individual and the economic emancipation of labor from the burdens of traditional society, the emergence of social thought was to make evident that this could not suffice to organize a stable modern society. There was a need for models of organization and social integration, i.e., for a 'science of social order.' For such a science, the first object of analysis has been the 'social question,' that is, the mass pauperism growing alongside the rise of modern liberalism that social thought regarded as a danger for social stability. This became particularly clear in France where revolutions brought the problem of popular poverty to the forefront of the political arena.

The Experience of the Revolution

The idea that the French Revolution played an important role in the rise of sociology has been established by important sociologists such as Reinhardt Bendix and Robert Nisbet. The very term 'social science' became official during the French Revolution through authors like Condorcet (Baker, 1964; McDonald, 1993). Less common is acknowledging that its development was linked to the question of poverty and the new political importance it assumed. The Revolution was more than an intellectual advance in rationalism; it was a dramatic experience cutting bridges with most of what was known and abruptly revealing the depth of the social crisis. The new awareness of the crisis, more than the rationalist critique, was crucial to social thought.

Nisbet (1943), stressing the impact of the French Revolution over the making of sociological concepts, suggested that the experience of the crisis focused them on the 'social group,' as their own response to eighteenth century social theory centered on the opposition between the state and the individual. Social thought developed by establishing the group as an object of science, not only with an ethical implication, but also with a primary theoretical value in the study of man.

Why the group? Because the impact of the Revolution upon traditional social groups had driven the crisis until the destruction of the whole institutional frame, eroding the very bases of social belonging. The 'rational state,' as Nisbet put it, that the eighteenth century social theory had been regarded as the solution to the crisis of traditional bonds (religion, family, guilds, and associations) and the correlation to individuals' emancipation, no longer seemed able to nourish a real sense of social belonging. The group raised a new problem that could not be faced in economic or in juridical terms: to rebuild society required new foundations for the social bond. The experience of the crisis and the condition of insecurity due to the destabilization of order opened the way to a science that would fill the task of laying down the proper conditions for a new social order.

The Autonomy of 'Society'

The 'social question' was the most dramatic evidence for both the crisis and the need for a new social order. Poverty could no longer be regarded as a mere individual condition to be dealt with by charitable support and police repression, as in the Old Regime treatment of mendicancy and vagrancy. The political emancipation gained through the Revolution, as well as the economic emancipation guaranteed by a free labor, made the increase of poverty among the urban popular masses an issue of public concern (Simmel, 1908). How could the poor play a role in the new social order, be inscribed in the political arena of universal citizenship and in the liberalized market of productive labor? As Hannah Arendt (1963) stressed, the social

question broke the social unanimity around the revolutionary project – and from then onward, it has been the stumbling block of any revolution.

The modern idea of rights, making the poor just citizens the same as everyone else, and the modern economic imperative to include them into productive labor, did converge in giving a new visibility to the social question. In fact, poverty challenged both the achievement of individual autonomy as well as the generalization of free labor. It was therefore important to act against the social causes of poverty, and therefore to know them, what neither legal nor economic sciences could do. The importance of the poverty question grew together with the political awareness that a stable society demanded an end to the revolution. Both social and political problems contributed to a realization that social change could not be understood through individual actions, but rather as the result of relatively impersonal processes. Society appeared to have autonomous conditions to its own development and an autonomous ability to resist changing, both impossible to curb by law or through the market.

The social question has been the first object of application where the autonomy of social thought's premises, concepts, and methods was at stake. It was thus the arena for a gradual autonomization of social thought from economic and legal categories, founding the problem of order as specifically social (Procacci, 1993). In this way, it represented a crucial step toward the construction of the very idea of society as a theoretical concept and at the same time a practical field of investigation.

The Science of Social Order

The analysis of the social question had a crucial impact over the making of positive sociology. With Saint-Simon and Comte, the search for a new social order was firmly located within antisocial effects of industrial transformation: how was it possible to organize inequality in a way that would not prevent social stability? Their foundation concepts were marked by their source in the analysis of social inequality.

Firstly, they carried a vision of society as an organic entity, essentially concerned with the cohesion of all its parts – hence the importance of the metaphor of social organism. Most importantly, this located sociology on the side of the whole social body, the common interest, the collective being – apart from the opposition opened by liberalism between individual and collective points of view.

Secondly, all dangers for social order were interpreted in the perspective of social pathology, calling for some kind of therapeutics. Poverty was a pathological element within the social body – the task of social thought was to identify the means for restoring a normal society. Hence the importance of medical knowledge, with the normative character intrinsic in the idea of restoring a normal society. Methods of inquiry were also drawn out of medical practice: observation of symptoms, collection of cases, and statistical recurrences. This shaped concepts animated fundamentally by a will to reform. There was no longer a pure science; the program of positive sociology was a science able to found the criteria for acting in order to improve human conditions on positive knowledge.

Thirdly, the foundation concepts of positive sociology inherited the moral element that had characterized the philanthropic approach to poverty. Particularly with Comte, the problem of order became a question of moral consistence of society, impossible to solve through legal or economic reforms. His main theoretical questions run about the position of bourgeoisie and the working class in the new social order (Elias, 1978). For this reason, once the revolution exploded again in 1848 and the popular movement claimed political and economic reforms to solve the social question, he felt the need to engage into the public debate. His 'Positivist Society,' created a few days after the February insurrection, had the explicit task to oppose the positivist view of the social question to socialists. Insufficient labor did not depend upon capitalist economy, but upon an irrational organization that scientific development would overcome. The emphasis was rather on society's moral engagement to fight against poverty, a problem more difficult to solve: it required to put 'social sentiment' in the forefront, by promoting a sociability that the Comtian concept of 'duty' was to organize as the cement for new social bonds.

Democracy and Socialism

A different perspective is the one opened by Tocqueville's analysis of democracy. Elected in 1848 to the parliament by the first universal manhood suffrage, he was directly involved in writing the new Constitution which was to put an end to the revolution. As such, he politically intervened against the reforms claimed by the popular movement. Political organization of democracy above all demanded fighting its tendency to ally with a centralized power. The social question implied such a danger, strengthening the state that was expected to solve it; therefore nothing could be granted, except an exclusively moral engagement of society to reduce poverty. Distinguishing moral duties (*la morale*) from legal rights (*le droit*) was strategic in preventing the state from becoming either an economic agent providing jobs or a regulator reviving old protectionism. A political solution could only come from organising democracy: pushing people to act on collective issues and promoting public virtue instead of private freedom, were the only means for undermining the spectre of state despotism. The perspective of self-government led to rehabilitate associations as the arena where people would exert their public responsibility and resist the state.

The 1848 revolution was a crucial moment for social thought consolidation through its analysis of the social question. The work of Lorenz von Stein (1850/1921) provided important evidence and was a crucial source for Marx. Indeed it would be difficult not to mention the influence of social question over socialist social thought, as the revolution of 1848 exemplified. The experience of French revolutions was also central for Marx's historical concept of class, conceptualizing the fundamental inequality producing poverty in a capitalist economy. But class conflict was for Marx (Marx and Engels, 1848/1964) the key to development, and not a pathology to be cured; there could not be any other solution to it but the revolution. The strategical program of Marxian social thought deeply differed from the one of sociology: it was not a question of reanimating society through moral duties and intermediary

associations. Under this light, there is more continuity with Durkheim's theory of social solidarity.

In his study on socialism, Durkheim (1895/1971) stressed its affinity with sociology, given the central role played by organization and a set of social rules controlling the economic sphere. Since societies autonomously tend toward solidarity, the antagonism between capital and labor was a danger, and could only result from disorganization. The social question was a problem of socialization; even unions might work as a means of social integration. The concept of organic solidarity combined the characteristics of positive sociology and the attempt to enhance democratic strategies: it provided criteria for techniques reorganizing social bonds, such as the division of labor and the resurgence of intermediary groups.

In conclusion, the analysis of poverty contributed to strengthen a critique of economic and legal individualism toward a new science of social solidarity. The impact of the social question tied the fate of social science to the development of an administrative state, and engaged it into the political arena; thus promoting the re-establishment within the social body of those groups that liberalism had strategically eliminated.

Social Referencing during Infancy and Early Childhood across Cultures

Christine Fawcett, Uppsala University, Uppsala, Sweden
Ulf Liszkowski, University of Hamburg, Hamburg, Germany

Abstract

The article reviews the state of knowledge on infants' social referencing. The developmental course of social referencing throughout infancy is described, as well as current debates on the motivation behind social referencing. Variation in social referencing depending on the type or information, information source, and characteristics of the infant are described. Finally, cultural variation and the presence of social referencing in nonhumans are discussed.

Classic Studies in Social Referencing

Social referencing describes the tendency to gather information from other individuals to regulate one's own behavior in ambiguous situations. Social referencing was first studied in adults (e.g., Asch, 1952; Schachter and Singer, 1962; Sherif, 1958), and until the 1980s, it was an open question whether infants would also show this behavior. Yet it seemed likely that they would, given that the literature on attachment, showing that infants see their caregivers as a secure base for exploration (e.g., Ainsworth et al., 1979) suggests that they could also see caregivers as a source of information about the world (Feinman and Lewis, 1983).

An additional motivation for studying social referencing in infants was to show that emotional expressions themselves were more than by-products of an emotional experience, but actually used as signals to others that could alter behavior (Sorce et al., 1985). If infants change their behavior based solely on the emotional expressions of others, then those expressions must have referential meaning. The emotion is about something in the world and thus can provide useful information for the infant.

In one of the earliest social referencing studies with infants, Feinman and Lewis (1983) examined 10-month-old infants' behavior toward a stranger when their mother gave positive or neutral signals about the person either directly to the infant or indirectly – when speaking to the stranger herself. They also measured infants' temperament and found that infants with an easy temperament who received direct positive information were more likely to approach the stranger. There were no other differences observed. However, it is possible that the situation was actually not ambiguous for most infants; thus the information from their caregiver did not lead them to adjust their behavior. That is, if infants know that a situation is safe or dangerous, they should not look for guidance from others.

The importance of uncertainty for social referencing was demonstrated by Sorce et al. (1985). Their study used a visual cliff with varying depths. That is, 12-month-old infants could cross from a normal-looking floor to a glass side with the floor seemingly close or far below them. When the floor was far, infants were unsure about whether crossing was safe and thus looked to their mother for information. If their mother's response was positive (i.e., a facial expression of happiness or interest), the majority of infants crossed the visual cliff. In contrast, if the mother's expression showed fear or anger, very few infants crossed. Their study also showed the importance of an ambiguous situation for social referencing to occur. If the floor of the visual cliff did not appear to drop off at all, infants crossed even when their mother's expression was of fear. In fact, infants rarely looked to her in this situation, and even those who did continued to cross, failing to change their behavior.

In another classic study, Hornik and Gunnar (1988) described the social referencing behavior of 12- and 18-month-old infants toward their caregiver in a more natural setting. This allowed them to examine the interplay of social referencing with other kinds of communication, such as affect sharing. Infants were presented with a rabbit in a cage and their behavior toward their mother was examined. The results showed that infants' referencing looks – those paired with a puzzled or wary facial expression – were as likely as affect-sharing looks when the rabbit was first introduced, and over time, referencing looks occurred much less often than sharing looks. This suggests that infants gather the information they need early on, but continue to want to share an experience with others over time. A second interesting finding from the study was that infants classified as initially wary or bold regarding the rabbit engaged in the same amount of referencing to the caregiver. This may show that social referencing can be used not only to seek valenced information (e.g., is it safe to approach?), but also instrumental information (e.g., what is this?) about an ambiguous situation.

This early work on social referencing in infancy served to establish several typical methodologies and to set the groundwork for future research that would more closely examine the process and development of social referencing.

The Developmental Course of Social Referencing

The first studies on social referencing focused on children around 1 year of age. How early do infants reference others for information when they are in ambiguous situations? A further question is whether referencing (i.e., seeking information) and behavioral regulation (i.e., acting on that information) develop at the same time.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23169-3

Earliest Evidence of Social Referencing

Using a cross-sectional design, Walden and Ogan (1988) explored the emergence of social referencing behaviors between 6 and 22 months of age. They found that at younger ages (6–9 months), infants were less discriminatory in their gaze to parents. When they looked at their parent, they did not always look to her face, suggesting that they may have only been checking that she was available, rather than looking for information. Younger infants also tended to look more to their parents when positive expressions were conveyed, whereas older infants (14–22 months) looked more to their parent's fearful expressions. Infants did not reliably regulate their behavior based on their parent's expression until between 10 and 13 months. At that age, infants were less likely to approach a toy after a fear reaction from the parent than a positive reaction. In addition, older infants were the only ones more likely to look to their parent before touching the toy. Interestingly, during a later free play trial after the parent was no longer giving emotional reactions, the older infants in their study (14–22 months) were actually more likely to touch the toy that had received a fear reaction, whereas the younger two groups were less likely to. In that situation, the toys were no longer moving or making noise and the experimenter invited infants to play with them. Thus, older infants may have inferred that the previously fearful toy was now safe. Together, this study suggests that social referencing behavior emerges around 1 year of age, but that it also continues to develop through the second year of life. Yet with a different experimental design, perhaps infants would be able to show social referencing at even earlier ages.

Until recently, the earliest evidence of behavioral regulation in response to other's emotional reactions was found at 8.5 months of age. Boccia and Campos (1989) found that infants were more wary of a stranger if their mother reacted with a stern rather than a cheerful greeting when the stranger entered the room. However, a recent study now shows that already by 5.5 months of age, infants are sensitive to emotion–object relations and regulate their own behavior based on those relations, but only for stimuli that had both facial and vocal emotional information (Vaillant-Molina and Bahrick, 2012). In a looking-time paradigm, infants demonstrated recognition of the specificity of another's emotional reactions by showing increased attention when the actor reversed her emotional reactions of happiness and fear to two different toys. Interestingly, they also preferred to touch the toy previously associated with a happy reaction. This suggests that they were also regulating their own behavior based on the actor's happy and fearful reactions, although they did not have to seek out the information as in typical social referencing paradigms. Another difference between this study and the standard ones is that it used habituation. Thus, the young infants were given as many repetitions of the emotional information as needed to fully process it. This extensive exposure could be one reason why infants were able to show social referencing ability at such a young age.

What Changes over Development?

Social referencing requires the ability to seek out information when needed, understand others' emotions, apply those emotions to objects or situations in the world, and to regulate behavior based on the information given. Infants' development in these areas can help give insight into when and how their social referencing develops and increases in sophistication.

Information-Seeking

Information-seeking may actually be one of the latest developing aspects of social referencing. Baldwin and Moses (1996) proposed that even though 12-month-old infants can make use of others' emotions to regulate their behavior, classic social referencing paradigms do not give clear evidence that infants actively seek out emotional information in an ambiguous situation. Instead, they may simply come across the information when they happen to look to an adult for other reasons, such as comfort-seeking or checking whether the caregiver is available. A likely prerequisite for information seeking is a concept of knowledge and ignorance. Infants must recognize that they lack information in an ambiguous situation and that another person may have useful information. It is an ongoing debate whether infants have stable concepts of knowledge and ignorance at 12 months of age (e.g., Liszkowski et al., 2008; Surian et al., 2007). Walden and Ogan (1988) found that only infants over 14 months of age are likely to check with their parent before approaching an ambiguous toy, even though younger infants' approach behavior is regulated by the caregiver's reaction.

A few studies have examined information-seeking, though not necessarily in a social-referencing context. Vaish et al. (2011) used an object-labeling paradigm and showed that 13- and 18-month-old infants were more likely to look to the person who labeled an object when it was necessary to disambiguate her label. That is, when two objects were available, infants checked her gaze to determine which one she was attending to, whereas when only one object was available, they were less likely to do so. Infants may also seek information when pointing at things (Baldwin and Moses, 1996; Liszkowski, 2005). Begus and Southgate (2012) looked at pointing behavior to determine whether infants seek information appropriately from others. They found that 16-month-olds were more likely to point to novel objects when interacting with a knowledgeable experimenter than an ignorant one, suggesting that they knew the knowledgeable person would be able to provide them with more information. While neither of these studies directly tested information-seeking in a social referencing paradigm, they do suggest that at least by early in the second year of life, infants can seek out information from others in a sophisticated way.

Emotion Recognition

Young infants are not yet able to approach and avoid situations in the same way as older infants can; however, sensitive measures of infants' attention can indicate some understanding of emotional reactions to objects. Hoehl et al. (2008) looked at whether very young infants' brain responses indicated that they were already sensitive to when another person reacted negatively to an object. They showed that infants' neural responses to objects differed if those objects had previously been shown in the context of a person gazing at the object with a negative emotional expression. This suggests that already at 3 months of age, infants can associate others' negative emotional reactions with objects and they

subsequently pay more attention to those objects, even when the emotional information is no longer visible.

The Hoehl et al. (2008) study only compared negative emotions to neutral expressions. Yet we also know that between 3 and 4 months of age, infants begin to discriminate between multimodal emotional expressions of happiness, anger, and sadness, as indicated by preferentially gazing at novel facial expressions in a habituation paradigm (Flom and Bahrick, 2007). By 7 months of age, infants also show increased attention for fearful facial expressions in that they have difficulty disengaging from a face with a fear expression (Peltola et al., 2008, 2009).

Studies on emotion differentiation cannot speak to whether infants recognize the meaning behind the expression they observe or whether infants' own emotional experience is affected in any way. Yet they show that infants have the first abilities necessary to begin learning more about the relevance of emotions in their world.

Referential Understanding

In addition to understanding what emotion another is expressing, social referencing requires that infants recognize the referent of the emotional reaction. Moses et al. (2001) showed that both 18- and 12-month-old infants appreciated the relevance of an emotional message when regulating their behavior toward an ambiguous toy. That is, an emotional reaction was delivered either by someone attending or not attending to the ambiguous toy. Infants were selective such that they differed in their approach to the toy based on positive and negative emotional reactions only for the toy to which the reaction was directed. For example, if the infant was examining one toy while the experimenter emoted toward a different toy, infants appropriately paired the reaction with the toy in the experimenter's view.

Repacholi (1998) also showed that 14- and 18-month-old infants have referential understanding of others' emotional reactions. Infants observed an adult gaze into each of two boxes and react positively to one and negatively to the other. Later, infants were more likely to explore the contents of the box that had been reacted to positively, even though they were equally likely to touch both boxes themselves. This suggests that infants accurately applied the emotional reactions of the adult to the contents of the box – even though they were not visible to the infant at the time – and not the box itself. Thus, early in the second year of life, infants seem to be able to accurately apply emotional messages to objects and situations.

Locomotion

A proposed factor influencing changes in social referencing around 8–9 months of age is the onset of crawling. Since crawling allows infants to be more independent from their caregivers, the need for social referencing and the distal communication it provides likely increases sharply once infants begin to crawl. Infants who have begun to crawl pay more attention to distant objects and check back with their caregiver more often than infants of the same age who are not yet crawling (Campos et al., 1992). Crawling infants also receive more prohibitions from their caregivers, particularly when the infant is far from the caregiver (Zumbahlen and Crawley, 1996). Together these findings from interview studies suggest that crawling may be a catalyst for social referencing behavior. In addition, infants with locomotor experience are more able to follow the referential gestures (gaze and pointing) of others, another important skill for social referencing (Campos et al., 2000).

There is also some evidence that the transition from crawling to walking could be influential in the development of social referencing. One study suggested that when infants begin to walk, they actually begin to socially reference less and engage in more social bidding than younger, crawling infants (Clearfield et al., 2008). However, it is possible that the novel toys used in that particular study may not have been sufficiently ambiguous to elicit social referencing behavior in the older, walking infants.

Can Mood Explain Social Referencing?

Given that evidence suggests that infants already understand the referential nature of emotion when they engage in social referencing, it is unlikely that mood can account for behavioral differences seen in social referencing situations. In addition, many studies have specifically ruled out mood as a confounding variable. For example, Hornik et al. (1987) found that caregivers' emotional reactions affected infants' behavior toward the particular toy that was the target of their reaction, but not to infants play behavior in general. Similarly, Feinman and Lewis (1983) accounted for mood by comparing infants' behavior toward a stranger (who had been reacted to either positively or negatively) to behavior toward their mother. Even when behavior toward their mother was subtracted, there was a difference in approach to the stranger based on the mother's expression, showing that mood and general willingness to approach another did not explain their findings. Walden and Ogan (1988) examined infants' own emotional expression during a social referencing task and again found no evidence that mood could be a confounding factor.

Finally, Stenberg and Hagekull (1997) directly tested the possibility of mood modification by having caregivers deliver either specific (directed to a particular object) or general positive or negative emotional messages. They found that while infants' behavior toward the toy was affected by the specific emotional messages, with more play following the positive than negative reaction, infants' overall activity was affected by the general emotional message. The findings suggest that when emotional information is specifically directed to an object, infants' own mood is not a factor in their behavior. In contrast, when general positive or negative emotional information is presented, infants do not have a clear target for that expression and react with overall differences in their exploratory behavior.

Whom Do Infants Prefer to Reference?

Do infants preferentially reference certain people over others? Research in this area has focused on infants' tendency to reference their caregivers compared to a familiar experimenter. The debate is rooted in the question of whether infants' looks

in ambiguous situations are information-seeking behaviors related to social referencing, or rather comfort-seeking behaviors related to attachment. In one such study, Zarbatany and Lamb (1985) presented infants with an unusual toy and either their mother or an experimenter was in the room posing fear or smiling expressions. Infants were found to reference both their mother and the experimenter, but their behavior toward the toy was only influenced by the reactions of the mother. When the experimenter was posing either expression, infants were unlikely to approach the toy. It was only when the mother showed a positive expression that they did so. A later study using a similar paradigm, but with both adults remaining in the room for the duration of the study, gave contrasting results. Infants both referenced the experimenter and regulated their behavior based on her reactions, with fewer and slower approaches to the toy following fear than smiling expressions (Klinnert et al., 1986). Thus, it is possible that infants in the Zarbatany and Lamb study were too uncomfortable in the room without their caregiver present that they were not able to approach the toy, even when the experimenter's expression was positive.

More recent studies have continued to find that infants tend to engage in more social referencing toward an experimenter than their caregiver. They do so not only when their parent is inattentive (Stenberg, 2003), but also when both parent and experimenter are providing information. Specifically, Walden and Kim (2005) presented 18- and 24-month-old infants with ambiguous toys and both caregiver and experimenter provided emotional reactions about the toy when infants looked toward them. They found that infants at both ages looked more toward the experimenter than their mother and that this difference was even greater for the 24-month-olds. Importantly, in a baseline looking measure, infants looked equally to their mother and the experimenter, ruling out overall interest in the experimenter as an explanation for the difference in referencing.

Stenberg (2009) found that infants' preference for referencing experimenters holds even when the caregiver is the one introducing the ambiguous toy and providing the emotional reaction about it. That study also looked specifically at 12-month-old infants' behavioral regulation following positive emotional reactions delivered by either the caregiver or experimenter. The findings showed that infants played longer with the toy following positive messages from the experimenter than the mother. However, since the study only included positive emotional reactions, it's not possible to say whether the pattern of findings would hold if the experimenter and caregiver were giving negative, rather than positive, messages.

Together, the findings suggest that infants may be relying on an inference of expertise when selecting whom to reference. That is, they look to the experimenter and trust her information more because they expect that the experimenter will know more about the ambiguous object or situation.

The Effect of Information Type on Social Referencing

What kind of information do infants use when socially referencing others? The modality of information – visual versus vocal, as well as the valence of the information being delivered could have differential effects on later behavioral regulation.

Modality

Multimodal emotional expressions – displayed with both facial and vocal information – are those earliest discriminated by infants. Flom and Bahrick (2007) showed that by 4 months of age, infants could discriminate multimodal expressions of happiness, sadness, and anger, and that they could only do so when temporal synchrony between the face and voice were intact. By 5 months, infants could discriminate the expressions with only vocal information and by 7 months they could do so with only visual information available. The same developmental trajectory for emotional expressions seems to be seen in social referencing. Twelve-month-old infants' crossing of a visual cliff was affected by multimodal and vocal emotional expressions, but not expressions of the face alone (Vaish and Striano, 2004).

In a more naturalistic study of the modality for social referencing messages, caregivers were asked to improvise their own emotional messages. Results showed that they tended to produce more gestures with messages of fear and more vocalizations with positive messages (Kim et al., 2010). Further, these differences were also what infants responded best to. They modified their behavior more based on multimodal and visual information in the case of fear and based on the amount of vocal information in the case of a positive message.

Even when the modality for an emotional message is video, infants regulate their behavior based on it. Specifically, Mumme and Fernald (2003) found that 12-month-old infants, but not 10-month-old infants, were less likely to touch a toy when they had seen someone on video react negatively toward it, compared to a toy that was reacted to positively or neutrally.

Valence

Are both positive and negative types of information valuable during social referencing? Vaish et al. (2008) propose that there is a negativity bias in social referencing, such that infants' behavior is more affected by negative than positive emotional reactions. When a neutral baseline is used as a comparison, most social referencing studies find little difference between infants' behavioral responses to positive versus neutral reactions from others, yet a significant difference between neutral and negative remains (e.g., Hornik et al., 1987; Mumme et al., 1996). This is important because it shows that social referencing may function primarily in one direction – encouraging infants to avoid objects and situations, but not to explore them.

Looking at valence from the caregiver's perspective, mothers naturally gave more intense positive reactions than negative ones when asked to improvise their own messages to infants (Kim et al., 2010). It could be that caregivers already know that a positive emotional message needs to be higher in intensity to influence their infant's behavior compared to a negative message.

Individual Differences in Social Referencing

Temperament

Findings on the relation between social referencing behavior and temperament have been somewhat mixed. Temperament refers to stable characteristics including emotional valence, fearfulness, inhibition, and ease of being comforted. It could be that infants who are more temperamentally fearful or less easily comforted would be more likely to reference others when encountering ambiguous situations or more likely to act on the information they receive during social referencing.

In one of the earliest studies on infant social referencing, Feinman and Lewis (1983) found that infants with easy, but not difficult temperaments increased proximity and offered more toys to a stranger following positive messages about the stranger from their mother. In contrast, Bradshaw et al. (1987) later found no relation between behavioral regulation during social referencing and positive/negative affect temperament, which corresponds to the easy/difficult dimension used by Feinman and Lewis. They did, however, find that infants with a more positive temperament made more social referencing looks to their caregiver.

Blackford and Walden (1998) investigated the role of temperamental fear on social referencing behavior. They found that low-fear 11- to 13-month-old infants were more likely to regulate their behavior based on positive or fearful messages from their caregiver regarding a novel toy than fearful infants who tended to avoid the toy altogether. Temperament did not have an effect on how often infants looked to their caregivers. Thus, the seeking of information remained the same, but the use of information differed for infants with different temperaments.

It is possible that the effect of temperament, at least fearful temperament, comes down to how ambiguous the experimental situation is for the infant. If the infant is temperamentally fearful, then he or she is already predisposed to avoid to the toy, despite a positive message from an adult. This is an important confound to keep in mind, since ambiguity is important for an accurate measure of social referencing.

Attachment Style

Social referencing and attachment are in some sense very closely intertwined. There is still some debate as to whether social referencing looks are actually comfort-seeking behavior, related to attachment, rather than information-seeking behavior (see Section Whom Do Infants Prefer to Reference? earlier in the article). However, even if social referencing is based on information-seeking, infants could differ in how likely they are to seek information from their caregiver depending on the quality of their attachment relationship. For example, in a study relating attachment security to referencing behavior, insecure-avoidant infants referenced their parent the least and insecure-resistant infants referenced the most, with securely attached infants in between (Dickstein et al., 1984). This is in line with the definitions of insecure attachment styles, in which avoidant infants tend to ignore their attachment figures, even in ambiguous situations, and resistant infants continue to seek comfort, but fail to actually be comforted by the attachment figure (Ainsworth et al., 1979).

Atypical Development

Children with autism spectrum disorder (ASD) tend to have significant deficits in social cognition, including social orienting, joint attention, and attention to others' distress (Dawson et al., 2004). Thus, it seems likely children with ASD would show impairments in social referencing. Sigman et al. (1992) found that 3- to 4-year-old children with ASD were less likely to respond to adults' emotional reactions than control participants, yet those who did respond regulated their behavior toward the toy accordingly. Their study could not examine referential looking, however, since the adult expressed an emotional reaction regardless of whether the child looked at her.

Since ASD is not typically diagnosed until 3 years of age, one recent study examined the social referencing abilities of infant siblings of children with ASD, who are themselves at high risk for developing the disorder (Cornew et al., 2012). For referential looking, infants who were later diagnosed as having autism were slower, and overall less likely, to spontaneously look to an adult when an ambigious toy was present, compared to typically developing infants. Interestingly, behavioral regulation based on others' emotional signals was found to be impaired in infant siblings of autistic children, regardless of whether they were later diagnosed with autism or not. Only typically developing control participants showed appropriate behavioral regulation in the study. The authors suggest that there may be a more subtle impairment present in the high-risk infants who do not develop ASD that accounts for their decreased social referencing.

Cultural Differences in Social Referencing

To our knowledge, no studies have specifically examined cross-cultural differences in social referencing. Even though cultures differ in their forms of communication, parenting practices, and social norms, some aspects of communication and emotion seem to be largely universal. For example, the expression and recognition of emotions (see Elfenbein and Ambady, 2002, for a review) and infants' reference to objects by pointing (Liszkowski et al., 2012) seem to be universal. In addition, an extensive study of early social cognitive skills in three cultures (Canada, India, and Peru) showed that gaze following and joint attention were not significantly different, despite widely varying parenting practices and social norms (Callaghan et al., 2011). Cultural differences have been reported in the frequency of mutual gaze in dyadic face-to-face interactions of parents and their young infants, with Nso parents engaging in less direct eye contact than German parents (Kärtner et al., 2010; Keller et al., 2011). However, it is unknown whether there is a relation between early mutual gaze and the later emergence of social referencing.

With little variation in the basic skills of emotion recognition, gaze following, and joint attention, it seems likely that social referencing would also be present cross-culturally. The primary difference in social referencing across cultures may rather be in the content of what children learn, rather than the use of referencing itself. That is, the mechanism of social

referencing may be universal, but the information gained through social referencing regarding what should be approached or avoided could depend on what culture the infant is a part of. A second possible difference could be in the individuals targeted during social referencing. For example, if children in some cultures spend more time with siblings than their parents (e.g., Harkness and Super, 1995), older children could be a more common source for social referencing information.

Social Referencing in Nonhumans

Social referencing does not seem to be an ability that is specific to human infants. Itakura (1995) observed mother–infant pairs of chimpanzees and found that infants were more likely to seek contact with their mother when novel objects were present, suggesting that they could be engaging in social referencing. In a more controlled experiment, similar to those used with infants, Russell et al. (1997) demonstrated that young chimpanzees made referential looks to a familiar human caregiver and modified their behavior toward novel toys based on the caregiver's reactions of happiness or fear.

Macaque monkeys were also found to develop social referencing behavior. Older (5- to 12-months), but not younger infant macaques made more looks to their mothers in the presence of a rubber snake than in a control condition with no snake present (Roberts et al., 2008). Yet when clear referential looks – looking to the mother directly before or after looking to the snake – were measured, only 13% of the macaques were found to engage in looking from the snake to their mother. Also, since the mother's emotional reaction could not be manipulated, it is not known whether the infant macaques also regulate their behavior based on her reaction. Yet this study does give some evidence that macaques look to their mothers when an ambiguous object is present, whether for information or comfort.

Domestic dogs were found to socially reference their owners regarding an ambiguous object (Merola et al., 2012a). All dogs in their study looked to their owner after looking at the ambiguous object, demonstrating robust referential looking. There was also some evidence for behavioral regulation in that dogs that received a negative message from their owners were more likely to stop moving around the room than those who received a positive message. Additionally, dogs were found to approach the object more if their owner also approached it than if their owner avoided it. In a later study, Merola et al. (2012b) found that dogs looked not only to their owner, but also to a stranger for social referencing. There was also clearer evidence for behavioral regulation in dogs, at least when the owner was providing the emotional message. Dogs that received a positive message were more likely to approach the object than those who received a negative message.

Together these studies show that several nonhuman species can engage in some aspects of social referencing. This is not altogether surprising given that primates and domestic dogs also show abilities related to social referencing, such as gaze following (e.g., Kaminski et al., 2009; Call et al., 1998). It remains to be seen whether other nonhuman species with sophisticated social cognitive skills, such as dolphins (Pack and Herman, 2006), also engage in social referencing.

Conclusions and Future Directions

Social referencing is an important part of how infants and young children learn about their world from social figures. From around the end of the first year, infants begin showing social referencing behavior – looking to others for guidance in ambiguous situations and regulating their behavior based on others' reactions. While social referencing is likely to be a universal skill, there are still individual, and possibly cultural variations. More work looking at these variations can help to give insight into the processes involved in developing social referencing and how it can be encouraged in children with autism, for example, who have impairments in this ability.

Abstract

The nature of adult close, communal, relationships is outlined. We define high quality, close, adult relationships in terms of the interpersonal processes that, ideally, characterize them rather than in terms of stability, satisfaction, or lack of conflict. We explain why it is desirable to define them in the former rather than the latter manner. Then, factors that result in people being attracted to one another and that motivate them to form such relationships are reviewed. Next, processes involved in initiating such relationships and the importance of, eventual, commitment to relational functioning are discussed. Placement of a communal relationship within a larger hierarchically arranged set of relationships is also discussed. Finally, we briefly touch on how a lack of trust in a potential or existing communal partner undermines the quality of these relationships.

What Is a Close Relationship?

Adults have many types of relationships: brief relationships with strangers, relationships with acquaintances, ones with people with whom they do business, as well as relationships that are commonly called *close* relationships. This article is about close adult relationships for it is these relationships, including friendships, romantic relationships, and family relationships, that have received the most research attention.

Whereas, people will readily agree that relationships with good friends, family members, and romantic relationships often exemplify close relationships; what does the term 'close' really mean? Researchers have suggested a variety of definitions.

One definition has to do with the degree to which each person is capable of influencing and does influence the other person's thoughts, feelings, and behavior (Berscheid et al., 1989; Rusbult and Van Lange, 2012). This definition picks up those relationships that most impact the nature of our hour-to-hour and day-to-day behavior, thoughts, emotions, and, in turn, well-being. This definition has proven useful for many purposes and, interestingly, it captures both our most important enemies, as well as most important friends (*see* Friendship during Adolescence and Cultural Variations; Friendship during Childhood and Cultural Variations).

Other researchers define closeness in terms of the extent to which each member assumes responsibility for promoting the welfare of the other member (Clark and Monin, 2006; Clark and Mills, 2012; Monin et al., 2008) or the, overlapping, extent to which people actually do understand, validate, and care for one another (Reis and Patrick, 1996; Reis and Shaver, 1988). Still others define closeness as the extent to which a partner's attributes, goals, and desires are considered to be a part of the self (Aron et al., 2004) or as the extent to which one is committed to a relationship defined as intending to stay in the relationship for whatever reason, be it satisfaction, lack of alternatives, past investments, or social or personal norms (Rusbult et al., 2006).

No one definition is 'correct.' The antecedents and consequences of each type of closeness differ and can (and should) be studied separately. All varieties of closeness likely contribute to a sense that a relationship is important.

For purposes of this article, successful closeness can be considered to consist in: (1) members being responsive to one another meaning that they support one another's welfare (Clark and Mills, 2012; Reis et al., 2004; Reis and Clark, 2013) and (2) members facilitating their own receipt of responsiveness from their partners by expecting, seeking, desiring, and accepting such responsiveness (Clark and Mills, 2012; Clark et al., 1998; Clark, 2011; *see* Welfare). Hallmarks of these relationships include support being given in response to partners' needs or desires and sometimes simply to signal care and, importantly, this support being given noncontingently. That is, the recipient does not owe the donor anything for responsiveness received (Clark and Mills, 1979). Needs are tracked and attended to (Clark et al., 1986) but just what has been actually given and received, ideally, is not (Clark, 1984).

These relationships are communal relationships (Clark and Mills, 2012). Among adults, they are typically mutual and symmetrical meaning that each person (friend, romantic partner) assumes about the same amount of responsibility for the other. Needs and desires as well as partner ability to meet them can differ so the actual giving and receipt of care may differ between partners.

Not All Communal Relationships Are Equally Strong

Successful communal relationships differ in the degree of responsibility members assume for partner welfare. These relationships vary in strength meaning that some close, communal relationships, entail members taking on extremely high levels of responsibility for one another's welfare (meaning that people expend extreme amounts of their own effort, time, and resources to enhance their partner's welfare) whereas the members of other, also communal, relationships take on more moderate or even low levels of such mutual responsibility but still treat those in a communal manner (Mills et al., 2004). Communal relationships of a variety of strengths can be successful for they can

operate on a communal basis (up to a level strength implicitly agreed and acted upon by both members).

Sometimes benefits that exceed that implicit level are given and accepted on a tit-for-tat or exchange basis. In emergency situations that upper bound may be violated.

Defining High-Quality Relationships in Terms of Good Interpersonal Processes

Trusting, noncontingent, and sustainable communal responsiveness can and does take on many forms: mutual tracking of needs and desires, expressions of one's emotions allowing partners to most easily infer needs and desires, efforts made to understand and validate partners, the giving and receiving care, and the inclusion of the partner and mutual engagement in satisfying activities. Whereas, much past work has suggested that high-quality close relationships can be defined in terms of their stability (persistence across time), high individual ratings of satisfaction, and/or absence of conflict, we suggest that use of such markers as indices of well-functioning communal relationships may often be flawed. First, not all stable relationships are happy ones. People often stay in poorly functioning relationships because they have poor alternatives or because they have invested much in the relationship that cannot be recouped (Rusbult, 1983). Second, people can be satisfied with a poor relationship because they have low standards (comparison levels) for the relationship given abusive past histories (Rusbult, 1983). Finally, conflict can be absent from a relationship simply because one person dominates over another who fears him or her. To evaluate relationships, therefore, it is best to directly observe whether they are characterized by trust, understanding, validation, and by acts taken to promote partner welfare given on a noncontingent basis along with an openness to reveal vulnerabilities and to accept help from one's partner.

Responsiveness Is a Key to the Existence of High-Quality Relationships, but What Is Responsiveness?

Communal care, often called responsiveness, takes many forms. A person can provide help to a partner in clear need by, say, helping him or her move his or her furniture into a new apartment. So too can care take the form of supporting one's partner in attaining his or her goals either actively by taking steps to support goal attainment such as helping a friend who wishes to get him or her license study for a driver's test or by giving a person time and space to pursue a good (Feeney, 2004; *see* Social Support, Psychology of). It can involve celebrating another person's successes, a process known as capitalization (Gable et al., 2004). It can involve satisfying a partner's need to belong by including him or her in conversations (Aron et al., 2000) or in games (Williams, 2007). Responsiveness also can be primarily symbolic. One partner, for instance, may tell a partner that he or she is a good friend, send a card, or simply smile at a partner's comments (Drigotas, 2002; Swann, 1987). Yet other forms of responsiveness involve putting up with a partner's bad behavior without reacting negatively, a process known as accommodation (Rusbult et al., 2005) or suppressing one's own needs when a partner has needs that surpass one's own.

Both giving and accepting care contribute to feelings of responsiveness in adult relationships. Another way to put this is to say that all behaviors that are intended to result in members of a relationship promoting one another's welfare contribute to responsiveness.

What Drives the Formation of Close Adult Relationships?

The existence of well-functioning communal relationships in a person's life contributes to that person's physical and mental well-being, a fact now well known and reported by psychologists and epidemiologists alike (e.g., Cacioppo et al., 2011).

From infancy on, we all have a need to belong, to connect with other, and to form supportive relationships (Mikulincer and Shaver, 2007; Baumeister and Leary, 1995; *see* Infancy and Childhood: Emotional Development). Indeed our own self-esteem appears to be based upon our acceptance by others (Leary and Baumeister, 2000). Thus, perhaps the most important factor motivating people to form new adult communal relationships is a current lack of a sufficient number of effectively functioning communal relationships resulting in feelings of loneliness. For instance, those who have lost a romantic partner will likely seek another. Those who leave one location to move to a new one will seek new, local, friends. A person who becomes estranged from one family member may turn toward initiating or, more likely, strengthening the communal relationship with another family member (*see* The Family as Institution). Supporting the claim that lack of sufficient number of communal relationships is a driving force toward forming new ones, researchers have found that reminding people of social rejections from a current partner, on average, increases their interest in meeting new people (Maner et al., 2007: studies 1 and 2; Williams and Sommer, 1997). Mirroring this, so too is it true commitment to current close relationship partners decreases both attention and attraction to new potential partners (Johnson and Rusbult, 1989; Lydon et al., 2003; Maner et al., 2009, 2008) and having a sufficient number of communal relationships with friends and family should reduce a drive to form new communal relationships.

Of course, once a person feels the drive to establish new communal relationships, that person must decide with whom to establish such a relationship. One important determinant of with whom adults form close, communal, relationships is kinship. People feel most responsiveness toward and expect most responsiveness from those with whom they have the closest biological ties (Monin et al., 2008). Attachment theorists suggest that parents and their infants are hardwired to form attachment bonds (which lead to noncontingent responsiveness caretakers) (Bowlby, 1969). Mothers experience surges in oxytocin at the birth of a child and also in conjunction with lactation that appears to assist them in bonding with their children (Feldman et al., 2007; *see* Prenatal and Infant Development: Overview, Current Trends, Future Directions). For their part, infants spontaneously cry when distressed eliciting care from caretakers. Moreover, their very cuteness (including

having large round heads and eyes) elicits both liking and care and precision in movement (Zebrowitz and Montepare, 1992; Sherman et al., 2009). These features, even when they occur on adult faces, elicit both judgments of physical attractiveness and responsiveness from others (Berry and McArthur, 1985). Culture also dictates high levels of responsiveness to kin as indicated in the saying, 'Blood runs thicker than water.'

Other factors also promote the formation of close relationships. Many have to do with qualities of the potential partner. People are attracted to physically attractive others (Eastwick and Finkel, 2008) an attribute that seems to consist in having features that are similar to the average of many faces (Langlois and Roggman, 1990; *see* Face Recognition, Psychological and Neural Aspects). This may be because averageness in this sense signals (or at least did signal in our evolutionary past) health and a lack of threat of contagion, and fertility (Langlois and Roggman, 1990: Thornhill and Gangestad, 1999; *see* Fertility Theory: Embodied-Capital Theory of Life History Evolution). Beyond this, researchers have found that people associate physical beauty with positive personality traits such as intelligence, popularity, and kindness (Dion et al., 1972). Something that may occur because people desire close relationships with attractive others and project that desire onto others (Lemay et al., 2010). So too may such inferences be based on the fact that, when people perceive partners to be attractive, they treat those partners in more positive ways which, in turn, brings out the best in those partners (Snyder et al., 1977). Finally, we may prefer attractive partners to others because they reflect positively on us when we are seen together (see Sigall and Landy, 1973 for men reflecting positively on women).

Perhaps the most mundane but simultaneously powerful determinant of becoming attracted toward others and, ultimately, forming close, responsive relationships with others is mere physical proximity. We are more likely to form close relationships with those who live quite close by to us than with others (Bossard, 1932; Festinger et al., 1950). Even very small differences in physical proximity can make in determining the formation of close relationships. We are more likely to form a relationship with a person in an apartment next door to us than merely two doors away (Festinger et al., 1950) and less likely to form relationships with someone seated next to us than one seat away or in our row of seats relative to another row (Back et al., 2008). Perhaps, this is because rejection hurts (MacDonald and Leary, 2005). Whereas it is natural and does not reveal one's interest in others or risk feeling rejected to talk with someone to whom one merely 'bumps into' whereas clearly making an effort to contact others reveals that one is trying to start a relationship and, therefore, makes one vulnerable to rejection. Protection from rejection may also be why another's liking for us is a potent determinant of our liking for that other (Lowe and Goldstein, 1970).

Other factors known to influence initial attraction include the other's similarity to us in attitudes, race, socioeconomic status, education, and activity preferences (Bryne, 1971; Newcomb, 1961; Klohnen and Luo, 2003; Singh et al., 2008); even similarity in birth date and name (Jones et al., 2004), familiarity (which may signal safety) (Moreland and Beach, 1992; Moreland and Zajonc, 1982), and attributes that remind us of people with whom we have had good (or bad) close relationships in the past (Andersen and Chen, 2002; Andersen et al., 1996).

How Do We Initiate, Then Maintain, Close Relationships?

Relationships with kin typically require little initiation and such relationships may be supported in ways that may have evolved (e.g., we may be hardwired to like physically similar people and to like familiar people) (*see* Partnership Formation and Dissolution in Western Societies). Other communal relationships, such as those with friends and romantic relationships, however, require complex dance of relationship initiation. After initial attraction has taken place, if we wish to establish a close, communal relationship we must promote ourselves as desirable relational partners while simultaneously evaluating the potential partner's communal attributes and protecting ourselves from the pain of potential rejection (Clark and Beck, 2011; Beck and Clark, 2010).

When it comes to self-promotion, recent research suggests that self-promotion featuring bragging about our own accomplishments or such things as our connections is not a good idea (Crocker and Canevello, 2008). Indeed, doing so to backfire makes people like the self-promoter less (Canevello and Crocker, 2010). Yet not that all self-promotion is bad; work on responsiveness suggests it just has to be the right sort of self-promotion. To initiate close, responsive relationships one must have compassionate goals. One must attend to opportunities to respond to the potential partner's needs, desires, and goals (Clark et al., 1986). Importantly, one must respond non-contingently (Clark and Mills, 1979). Then if the potential partner accepts one's responsiveness and shows signs of increased liking one can up one's responsiveness and, importantly begin seeking support as well. In fact, early in potential relationships people do seem especially likely to strategically present themselves as communally oriented. They are especially like offering help to others (relative to seeking it) (Beck and Clark, 2009b), and especially likely to bend over backward to appear not to be keeping track of just who has contributed what to a relationship lest responsiveness appear to be contingent (Clark, 1984).

Responsiveness typically drops off somewhat as relationships form, people come to trust in another's care, and they feel less need to strategically present themselves as communal in nature (Clark et al., 2010). In other words, they seem to relax a bit. After some work at promoting oneself as a caring person there comes a point at which one reveals vulnerabilities (as, for instance, by displaying emotion) and can observe how the other responds. This is known as entering a socially diagnostic situation (Beck and Clark, 2009a), and it is crucial to being able to evaluate a partner's interest in caring for the self. Of course entering or creating one's own socially diagnostic situations is also crucial to acquiring support and developing a communal relationship. Graham et al. (2008), for instance, have shown how revealing one's negative emotions indicative of needs (e.g., fear, sadness, anxiety) can elicit help and, in turn, promote the development of close, communal, relationships and as well as the development of intimacy in the closest of those

relationships. Both self-promotion and evaluating of a partner will, likely, be accompanied by a good dose of self-protection. Yet if all goes well, the person succeeds in convincing a partner that he or she is a good partner, decides that the other is a good partner as well and begins to drop the self-protection.

Making a Commitment Matters

A few close, typically kinship-based, communal relationships start with a commitment (as when a child is born and parents feel an instant commitment to care for that child across decades). However, most close, adult close relationships begin without a commitment even though people do quickly behave in communal ways in order to establish a relationship (Berg and Clark, 1986). Commitment, if it comes, comes later when higher levels of trust have been established. Commitments, when they are made, consist in decisions to stay in the relationship over the long term. Commitment is accompanied, ideally, with a drop in efforts to strategically self-present, the absence of continuing deliberations about whether to pursue the relationship or not, and letting go of self-protection (Beck and Clark, 2009a, 2010). The relationship then ideally moves to its members simply attending to one another's welfare and being appropriately responsive, conveying one's own state of welfare to the partner, and seeking and accepting appropriate responsiveness as needed. In addition and importantly, when neither person has pressing needs, mutually enjoyable and beneficial activities take place.

Ongoing Committed, Close, Communal Relationships

Ideally, communal relationships are characterized by trust, understanding, caring, support seeking, and engagement in mutually enjoyable activities. Members track each other's needs (Clark et al., 1986), understand and validate each other (Reis and Shaver, 1988), help each other, and feel good about doing so (Clark et al., 1987; Williamson and Clark, 1989, 1992) and bad when they fail to do so (Williamson et al., 1996). Members put up with partner anger without dropping liking and forgive partners (Finkel and Campbell, 2001; McCullough, 2000; Rusbult et al., 1991; Yoo et al., 2011). They are even biased toward seeing partner faults as virtues (Murray and Holmes, 1993) and hold positive illusions about one another which may become self-fulfilling prophecies (Murray and Holmes, 1997; Murray et al., 1996a,b; Murray et al., 2000). They also, seemingly automatically, protect their relationships by not being attentive to attractive alternatives to their relationship (Maner et al., 2009), and viewing their own relationship as being better than those of others (Johnson and Rusbult, 1989; Simpson et al., 1990; Van Lange and Rusbult, 1995). Such successful relationships are called, variously, communal relationships, responsive relationships, and secure relationships.

Adult Close Relationships Occur within Sets of Other Close Relationships

More frequent and appropriate responsiveness makes for better close relationships. Yet it is important to keep in mind that high-quality communal relationships can and do vary in strength (Mills et al., 2004) and that people tend to have more than one of these relationships. Very strong ones involve responsiveness that can be very costly to the responding partner in terms of time, money, and effort. These very strong communal relationships often include relationships with one's children, spouse, parents, and the closet of friends.

There is a limit to the number of close responsive relationships a person can have. People cannot be responsive to all other people's needs; they also do not need everyone to be responsive to their needs. People generally have very few, very strong communal relationships, more moderately strong ones, more casual communal relationships, and many very weak communal relationships (Clark and Mills, 2012).

The moderate and even weak communal ones characterized by expectations of more limited and less costly responsiveness but they are, nonetheless, of value and can be very successful. Members of such relationships simply must implicitly agree on the strength of the communal relationship they have or desire and their actions should fall in the appropriate bounds. For instance, casual friend ought not to give the partner an extravagant present. That would make the partner uncomfortable and threaten the relationship. Those who have weak or moderately strong or weak communal relationships also can and do understand when partners must attend to the needs of someone with whom that partner has a stronger communal relationship as, for instance, might happen when a friend says he or she cannot attend one's birthday party because his or her child is ill.

Importantly, people are responsible for their own needs and they implicitly place themselves in their own hierarchy of communal relationships. Well-adjusted people place themselves high in their hierarchies but often have one or a small number of others, for instance, a spouse or child, who they rank equally with themselves or even above themselves. It is these people for whom they are most likely to make large sacrifices or to forgive large transgressions (Clark and Mills, 2012b).

Abilities and Fortitudes Necessary to Pull off Closeness

We have emphasized success in adult relationships. Yet many people fail to achieve success in these relationships and a great deal of the scientific literature on close relationships has focused and continues to focus on impediments to forming and maintaining close relationships. There now is wide consensus that viewing the self and others positively and trusting that others can and will care for one noncontingently is a key to becoming involved in close relationships and to succeeding in them (Murray et al., 2006; Murray and Holmes, 2011). Absent confidence that others will be responsive to one and that they will accept one's responsive overtures, little support will be sought or given. Individuals who lack such confidence have been called, variously, rejection sensitive (Downey and Feldman, 1996), insecure in anxious and/or avoidant ways, or low in self-esteem (Murray et al., 2000), low in communal orientation (Clark et al., 1987). Such people appear to be chronically relationally (and defensively) self-focused meaning that they think about themselves and implications of partner for themselves constantly and have trouble allowing self-protection and focus to fade to the

background when situations call for focusing attention on partners or joint activities such as conversations, dancing, work projects that are best accomplished if people focus neither on self nor partner but on the joint activity itself (Clark et al., 2008). As a result they often neglect partners and activities and overreact to real or imagined slights, fail to enter or create situations in which they will find out that others care about them (Beck and Clark, 2009a), view others in negatively biased and often incorrect ways (Clark and Beck, 2011), and react to others' anxiety by withdrawing from them rather than providing support (Simpson et al., 1992). They may even strike out at the partners in defensive and relationship defeating ways (Murray et al., 2003). As this happens some partners may compensate striving to insure the insecure person's security (Lemay, in press). Yet this is likely at a cost to the self and the relationship and partners, at times, will withdraw.

A full discussion of how close relationships fail to be formed, fail to be adequately maintained and disintegrate is beyond the scope of this article (*see* Partnership Formation and Dissolution in Western Societies). The important point is that successful close relationships require not only knowing implicitly or explicitly what the norms of close relationships are and what is required (something most people likely know but may not see as unattainable), but also having trust in others' positive regard for the self that provides the fortitude one needs to venture forth into relationships, risk dependence, and follow those norms without fear (Murray and Holmes, 2011).

Summary

Close, communal, relationships consist in mutual intimacy (including understanding and validation of one another) and both giving and seeking responsiveness. They promote the mental and physical well-being of their members. Although poor relationships are often characterized by a lack of stability and conflict and low satisfaction, stability, lack of conflict and satisfaction are not necessarily indicative of high-quality close relationships. Rather researches the interpersonal processes involved in the provision and seeking of constructive responsiveness in these relationships (and the lack of destructive interpersonal processes) to assess whether a high quality close, communal, relationship exists.

Social Resilience in Post-Tsunami Japan

Jin Sato, The University of Tokyo, Tokyo, Japan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A disaster of unprecedented magnitude hit Japan in March 2011 when a massive tsunami slammed into the country's northeastern region. In the face of that tragedy, the people of Japan demonstrated remarkable resilience, and using the concept of 'resilience' as our guide, this article attempts to draw lessons from that experience. To do so, the article analyzes the structural conditions of certain affected regions that made them particularly vulnerable. It also proposes to suggest ways to encourage societies to help prepare for future disasters by learning to take advantage of less visible, often untapped potential within the community.

Diverse Disaster Experiences

Nearly 20 000 people were killed by the tsunami of 11 March 2011 and more than a year later 100 000 inhabitants were still displaced from their homes. Describing the magnitude of the disaster only in terms of quantifiable dimensions does not do justice to the many deep-rooted and hidden aspects of the tragedy: thousands of farmers losing their livestock and land, forcing them to abandon their once proud profession; whole villages relocated to resettlement sites where they faced discrimination; countless elders transplanted away from familiar surroundings of home and family, loneliness adding to their grief; families forced to leave friends and pets behind during evacuation. Even those who may be considered as 'lucky' for being allowed to return to their homes still face enormous challenges in attempts to restore their communities. The lack of employment opportunities is a major issue, as is the shortage of space particularly in Fukushima for storing decontaminated debris. Although outsiders tend to consider 'victims' and 'affected areas' as uniform entities, these regions themselves are characterized by enormous diversity with respect to culture, economy, and the damage induced by the tsunami.

Victims of the nuclear disaster in Fukushima, on the other hand, were concerned with totally different issues. Initially, the government failed to publicize the exact extent of nuclear contamination, and many children were exposed to high levels of radiation during the first few days; consequently, their future lives will always be tainted by the fear of possible health effects. Marriage for young women in Fukushima may face obstacles due to the unfounded rumor that their genes may be defective because of radiation, not to mention the worries of pregnant women. People are just beginning to comprehend the full extent of the uncertainties caused by the tsunami, and that they must confront these issues for at least the next few generations.

The flipside of this tragic prospect is the remarkable resilience of the people in their daily survival: "the capacity of a system to absorb disturbance and reorganize while undergoing change so as to still retain essentially the same function, structure, identity, and feedbacks" (Walker et al., 2004). In the context of a disaster, resilience signifies flexibility of the social system, the ability to 'resile from' or 'spring back' from a shock (UNISDR, 2009).

In the aftermath of the tsunami, the most important 'resource' was the network of people and the information conveyed through personal links and contacts with neighbors. This was particularly important in establishing communications to distant villages when electric and phone lines were down. For example, neighboring communities and municipalities, rather than the central or prefectural governments, were the first to provide food aid, prompting many victims to claim that having been without food for a few days, they would always remember the taste of the first rice ball (Tokyo Foundation, 2012). Local moving companies, able to take advantage of their knowledge of the roads and the availability of their vehicles, helped to transport emergency goods; furniture companies provided basic supplies to restart lives in the evacuation centers. Disaster of the magnitude of the 3/11 tsunami and the subsequent nuclear accident in Fukushima can be seen as a true test of how people, communities, and the state can pool their diverse resources, either as a planned or spontaneous effort, to support victims to carry on in the face of extreme shock.

The purpose of this article is to learn from this unprecedented disaster, applying resilience as our guiding concept. Let me hasten to add that identification of these lessons is, by definition, a political endeavor that involves the arbitrary decision of what constitutes important factors. My approach here is not to single out numerous individual lessons, classify them, and attach labels to each. Instead, I examine the context or background, which induced the particular events that helped to strengthen or weaken the resilience of the people.

The Making of Tohoku, a Disaster-Affected Region

Yamauchi (2012) argues that even more than a year after 3/11, most Japanese are yet to recognize that the country has lost a part of its capacity to supply such national essentials as energy and rice. While general consideration of resilience tends to focus on the actors and their behavior, I shall begin by taking note of the circumstances in one particular region, Tohoku, which gave rise to the type of livelihood that made the district very vulnerable to external shocks.

How was the region of Tohoku (literally meaning 'northeast') formed during the modernizing process of Japan? In August 1945 after the termination of the war against the Allied Powers, the immediate problem for democratized Japan was food supply, as the country had lost about 40% of its territory, including Korea and Taiwan, which had produced significant

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64044-8

amounts of rice for consumption on the mainland. Daily rations (consisting of rice, sugar, salt, tobacco, etc.) imposed by the government from 1946 to 1947 were usually less than half the minimum (2160 calories) considered to constitute an adequate diet (General Headquarters, 1949). With a considerable decline in the male population because of the war effort, and with productive capacity completely skewed, domestic capacity to produce food decreased roughly 40% compared to peace-time production levels (Yamauchi, 2011: p. 257).

A Harvard geographer, Edward Ackerman, who came to Japan as a technical advisor to the Supreme Commander of Allied Powers noted at the time (Ackerman, 1949: p. 7):

> On the basis of my travels and studies, I can say that even a "well-to-do" person in Japan today lacks most things a middle class American deems a necessity of life Heat in the winter is one. The lot of average man is one of continual hard labour, if a family is to be kept fed, clothed and housed in even a minimal manner. A house without heat, a diet without variety is the lot of the majority … He furnishes only the margin between hunger and life.

Expansion of rice fields in the inland periphery was encouraged, and Tohoku became the prime target for saving the nation from potential famine. This policy was promoted through such infrastructure development as irrigation systems and the introduction of improved fertilizers. Present-day Tohoku is not only a major supplier of rice (26%), but also the source of abundant marine products, accounting in 2008 for 14.5% of fishery products and 11.2% of aquaculture products (Ministry of Agriculture, Forestry and Fisheries, 2009), both of which make up the very foundation of the basic diet of Japanese people.

Food was not the only concern; the general mobilization period of the 1930s in preparation for war had focused on Tohoku to develop it as a major supply center for labor and energy (Oguma, 2011). It was only in 1966 that Japan was able to reach self-sufficiency in rice, at which time the government ironically began to suppress production in order to reduce oversupply. Labor was another important resource to be supplied by Tohoku, and students straight out of school flocked into its cities to meet the labor demand during the high economic growth period from the 1950s onwards.

It was exactly these characteristics that pushed Tohoku in a particular direction. The Japanese government has gradually 'colonized' Tohoku since the war to serve its objectives. Unlike external colonization, which involves a military invasion of an outside territory, 'internal colonization' is characterized by the region's eventual willingness to be integrated with the empire, i.e., the periphery willingly accepts its specific role within the political economy of a nation (Kainuma, 2011).

In fact, central authorities in Tokyo had long had the unfulfilled ambition to bring the countryside under its control. Despite efforts to send preappointed governors from the Home Ministry to each prefecture, internal colonization during the Meiji era had not succeeded, since there was no 'material' necessity or benefit for the localities to follow the direction set by Tokyo. Internal colonization, which had been triggered by introduction of the 'general mobilization' efforts for external war purposes in the 1930s, resulted in the structural delineation of Tohoku suppliers and the Tokyo consumers in electric power and food. Nuclear plants became the magical tool for creating employment *in situ*, the periphery no longer needed to rely on cities for employment. Furthermore, nuclear plants made it possible to counter-balance power relations: the countryside, being the 'center' of electricity, was prioritized over cities (Kainuma, 2011). With time, nuclear power plants became an indispensable part of the nation's economy that had been achieved through the 'automatic' subordination of the peripheries. Oguma (2011) concludes that the real reconstruction of Tohoku after 3/11 will require dismantling the legacy of center–periphery structure that dates back to the 1930s.

What should have been foreseen was the creation of a structure that triggered inequality and domination because of the country-side's importance in the production of food and energy. Yet only a few dared to address this problem, since the major constituents of the game, i.e., electricity companies and plant-recipient communities or 'villages' that were made up of comrades loyal to the system, gained from this relation and were thus happy. This structure of inequality was another, albeit hidden, element of stifled diversity.

Examples of Local Resilience

It may be useful to put the concept of 'resilience' back in its original place and discuss the ecological foundation of social resilience. As was already pointed out, the main characteristic of the region devastated by the 3/11 tsunami was its concentration of farmers and fishermen, i.e., people working in the primary industry. This had a double effect after 3/11. Some farmers, faced with considerable equipment losses and salt-water soaked rice fields, took this as an opportunity to quit their business, while others with help from outside organizations found innovative ways to recover. For example, in Onagawa town of the Miyagi prefecture, a 'welfare agriculture' project was developed. This involved labor-intensive vinyl greenhouses for growing tomatoes. Instead of aiming for profit and production, the program's main goal was to facilitate communications, encourage exercise, and to give the elderly and pensioners something to do. Unlike other communities facing difficulties in rebuilding themselves, civic movement in Onagawa is strong and innovative.

For many of the fishermen who had lost their boats and equipment, the tsunami-induced devastation was the impetus to give up, a thought they might have had for several years because the younger generation was unwilling to continue the family tradition of fishing, preferring to move to the cities. For others, despite the losses, the remarkable revival of water quality and marine life held promise and strengthened their determination to restart more sustainable fisheries.

Forests are Longing for the Sea, the Sea is Longing for the Forests

Perhaps one of the most famous innovations by the local people in the disaster-affected regions is the "forests are longing for the sea" movement, which is a tree-planting

project to regenerate the forests. Led by the charismatic Shigeatsu Hatakeyama, the project has been in effect in the Kesennuma area since 1989 when he and his colleagues began planting broadleaf trees upstream of the Okawa River to promote forest drainage. To date, the group has planted more than 30 000 trees. This has had a visible impact on the water quality downstream and the Kesennuma Bay. As Hatakeyama notes (2012) "The fishermen look ashore to the mountain forests as their guiding post when they return home from their trips". The activities under its catchy slogan – "forests are longing for the sea" – has accumulated considerable respect both domestically and internationally.

This local movement extends beyond the act of simply planting trees and reviving the weakening link between the forests and the sea. Oyster farmers, by nature of their profession, are considered over the purity of the river water, essential for growing oysters. As a result of economic growth and improvements in living standards, the coastal environment has deteriorated, with pollution entering the river from sewage, agricultural wastewater, and oil spreading from fishing processing facilities. This resulted in an outbreak of red tide plankton in the 1970s, causing the oyster meat to turn red in color, which decreased its market value. The successful campaign led by the fishermen resulted in halting the dam construction in the upstream as well cancelling regional development plans for large-scale forest cutting and land reclamation.

The impressive and dynamic efforts of the oyster farmers have also become an effective educational tool for understanding the vague and elusive relationship between resources and the environment (Oh, 2013). The project has served as an example for children to learn about the unity of nature and how forest deterioration and river pollution damage the fisheries. This enhanced mutual concern and communication between families living in the coastal and mountain areas. The movement, although originally implemented to restore the region's ecology, became an important symbol of public involvement during posttsunami reconstruction, particularly during protest against the government plan to install a high seawall to protect against future tsunamis. The concept of "the sea is longing for the forest" resonated well with the post-Fukushima shift in public awareness against hi-tech with more emphasis on making the best use of surrounding nature and environment. Now, many NGOs and civic organizations, both domestic and international, are supporting this locally initiated activity.

The Miracle of Kamaishi

After 3/11, foreign media praised the resilience of the people in Tohoku, and reported on how 'disciplined' the tsunami victims were. Reporters were particularly impressed by the people quietly lining up in cold weather, waiting for food and water without bickering or conflict. One of the most celebrated example of 'discipline' was the so-called the Miracle of Kamaishi.

For the last 7 years, schools in Kamaishi have taught the basics of evacuation by inviting experts on disaster management to speak to the students. The golden rules drilled into the children were "Don't make assumptions about disasters" and "Put yourself first and flee". The rather unconventional ethics of helping yourself before helping others was a reflection of a hard lesson learned from the repeated tsunami in the region, carried over from their ancestors. Although Kamaishi was struck by the catastrophic tsunami on 3/11, the majority of its 3000 primary and middle-school children survived, having decided on their own that it would be risky to take shelter at designated evacuation sites, choosing, instead, to flee to higher ground to escape the incoming wave. Many lives *elsewhere* were lost because people went out to search for their families instead of following this rule to flee. Fleeing on your own, and trusting that others are doing the same, requires courage. The students' actions were encouraged by their awareness of the dangers of the tsunami and how it behaves, but also by their successful application of this knowledge that had been a part of the school's routine curriculum.

Discipline and Security

Michel Foucault (2009) once made a useful distinction between 'discipline' and 'security'. Both of these concepts, which shall be explained below, are critical in understanding how we address disaster of abnormal scale, i.e., extreme events that from a statistical point of view are expected to occur only once in 1000 years.

The classical system of order implemented through legal codes was based on the concept of 'the permitted' and 'the forbidden': "don't do this, don't do that" in a binary form along with a certain gradation of punishment. According to Foucault, the modern system of governance, on the other hand, requires a series of supervisions, inspections, and various controls before a crime is even committed. This shift in the techniques of governance has allowed the penetration of power to individuals as 'disciplines'. 'Security', on the other hand, is concerned with the macro effects of individual behavior, and is summarized by such questions as the average crime rate, what factors might affect the increase or decrease of such rates, and perhaps most importantly, at what costs. The goal, therefore, is to identify "socially and economically acceptable limits and around an average that will be considered as optimal for a given social functioning" (Foucault, 2009: p. 5).

The distinction here is not just the perception of the source of the control and its intensity; rather it is the origin of the norm and how it could be internalized back into the hands of individuals. While discipline originates from a particular norm at the level of the individual and his soul, security comes from external probabilities, the sources of which that cannot be directly perceived: the probability of a traffic accident, typhoon, tsunami, etc.

What was the relation between security and discipline in the context of 3/11? I have argued that the basic foundation of this phenomenon was structured through Japan's strategy for economic development. Both security and discipline originate from the identical source of values. Whether individually or collectively, someone at the center of the decision-making progress will decide and deploy what is to be done, or more precisely, what is to be prohibited. In the case of the tsunami, decisions were related to which evacuation center was to be

used, where not to go, whose instructions should obeyed, etc. Many did comply with government instructions, perhaps too strictly, and subsequently became exposed to extreme danger. There is no way to verify how many lives could have been saved if people had relied on their own intuition. The point is that people had been disciplined *not to think* independently but to follow the collective 'trend'. The Miracle of Kamaishi was perhaps a rare case where traditional tsunami ethics of 'think independently' was successfully disciplined into children's behavior via collective education.

But what about the thousands of people who were misled by government information about wind direction and possible areas of nuclear contamination? While we can be taught certain safety procedures with regard to imminent danger from a tsunami, for instance, information on and attitudes toward such risks as nuclear pollution cannot be initiated by the locals alone. As with risks related to climate or epidemics, norms must be developed externally and communicated to individuals on the ground. Norms for external risks that are hard to detect (such as nuclear risk) must be determined externally, and this usually means the government must play the role. The critical point, thus, is how can this vertical communications flow be conducted to make certain that people eventually have sufficient information and knowledge for making the right decision at the right moment.

Sources of Spontaneous Resilience

Resilience constitutes perhaps more than just the strategic allocation of resources that enables populations to deal with disasters. It may also encompass a previously unrecognized 'space', apparently unoccupied, that could become the critical buffer when a society faces tragic choices.

The long tradition of top-down industrial policies has strengthened Japan's strong public reliance on central government and bureaucrats. The minimal development of civil organizations such as NGOs and NPOs independent from the government is one such indication (Sato, 2010). Ironically, Japan needed two disasters to realize the importance of responsible civic forces. The 1995 Great Hanshin earthquake gave birth for the first time to the nationwide culture of 'volunteerism', while the 3/11 tsunami and ensuring distrust of the government because of their poor response gave rise to various types of self-help movements. Mutual assistance at the communal level is not new in Japan. However, these national-scale disasters nurtured a cross-border (i.e., cross-prefectural) culture of organizational assistance, which resulted in an enriched informational environment, allowing people to seek independent sources of information, thus avoiding total reliance on government announcements.

For example, many of the Buddhist temples in tsunami-damaged regions took in evacuees even though they were not the officially designated evacuation centers. Many of the official centers had, in fact, been completely destroyed due to the overly optimistic predictions of tsunami penetration. During total collapse of the official radio system in the town of Ohtsuchi, many amateur radio operators helped to alert the community to evacuate (Asahi Shinbun, 2012). According to the statistics compiled by the Cabinet Office as of October 2012, there are currently more than 150 NPOs established *outside* the Fukushima prefecture to assist victims of Fukushima. These provide bus services at temporary housing areas, monitor radiation levels, set up children's playgrounds, and offer professional health counselling. This assistance tends to be smaller in scale than the official government-provided projects, but it is mobile and reaches those with specific needs in a timely manner. Naturally, these organizations are confronted with challenges of their own: now that 3/11 is increasingly fading away as an event of the past, donations to these NGOs are diminishing, which threatens the continuity of their activities.

The argument here is that it is not possible to be directly involved in nurturing resilience, since an important part of resilience constitutes an intangible capacity scattered within a society. What we could do, instead, is to offer an environment where this capacity can easily be summoned when necessary to play an effective role in minimizing external shocks. I propose that in order for a society to become resilient, it must embrace plurality, and value social change and development. A single criterion, such as efficiency, which has occupied an increasingly dogmatic position in all spheres of Japanese economy, should not downplay the other criteria for a livable society. Next I elaborate on some principles that are relevant in designing such an environment.

Building an Environment for Resilience

According to the UN, "resilience of a community in respect to potential hazard events is determined by the degree to which the community has the necessary resources and is capable of organizing itself both prior to and during times of need" (UNISDR, 2009: p. 24). I agree, but the point is how do we know what is 'necessary' and how can we invoke the right resources at the right moment? As we have seen, apparently unrelated factors to disasters turned out to be useful and often critical for survival. Planners must be aware of its own limitations.

In discussing how things could have been better in the face of the 3/11 tsunami, I wish to highlight three critical dimensions of developing a resilient society: scale, speed, and a sense of ownership.

Scale

Striking among the disaster-affected areas was the fact that almost no community could have survived without external assistance. This stark reality has been motivated by the economy of scale. While each primary-industry sector, such as forestry and fisheries, may define their own boundaries through quotas and rules so as to keep resource exploitation within an acceptable range, techniques to minimize transportation distances have encouraged the unlimited application of the scale principle, making it more economical, for example, to import timber from abroad. Geographical distance per se is no longer a significant factor in transporting a good from one place to another; it is the economic cost involved in such transaction that matters. No wonder forestry is not anymore a feasible industry in Japan, despite the country's 70% forest

cover. Economic consideration is important, but we must recognize other values and principles as well. In order to diversify values and decision-making authority accordingly, officials need to reconsider whether the scale of development is appropriate. The tsunami experience has highlighted once again the value of self-supporting, if not self-sufficient, local units that can utilize diverse resources from local origins. Decentralization should be encouraged not only from a political, administrative, and economic perspective, but also from the point of strengthening local capacities to sustain themselves.

Speed of Development

Unlike the question of scale that attracts considerable attention in all investment decisions, the issue of speed of development and social change is seldom on the agenda. How can a society cope with and pay for preparations for an event that might occur only once in 1000 years? The general timeline of human action is often constrained by our own life span, and cycle of planning. State projects are usually planned for 3–5 years in accordance with the expected life span of the institutions. Education plans usually have a longer vision, perhaps 10–20 years. Pension and social security issues require an even longer vision but still fall within the range of 2–3 generations.

Perhaps the longest projection within our material culture concerns natural resource planning, particularly forestry, where trees requiring 50–60 years to mature can be expected to be logged by the next generation. In fact in the field of natural resources, adjusting speed or duration has been actively sought after. There are restrictions on resource use in many communal resource management schemes that limit the types of tools permitted, or the length of time that resources can be collected, in order to give resources time to regenerate to avoid depletion. Thus, controlling the utilization rate of resources can be critical for the survival of a community that is heavily dependent on surrounding resources. For these reasons, builders of resilient society have good reasons to listen to people working in the renewable resource sectors.

Sense of Direction and Ownership

The third and perhaps the most vital criterion is an adequate sense of direction; in other words, a vision for the future. Should civilization be guided by the logic of capitalism and market economy? Or should some wise leader guide us toward a fair and equitable society? Again, this criterion should also embody a kind of self-assessment meter that would signal when the directives become extreme. Citizens, facing the tsunami, felt helplessness as individuals – not because of their lack of capacity or resources – but because the decision-making process had long been handed over to the central authority, as exemplified by the fact that the Japanese have no voice in selecting the electricity company they wish to use, regardless of an individual's preference with respect to how his or her electricity should be generated. The 3/11 tsunami has certainly made it clear that local people need, once again, to reclaim ownership for themselves. But this ownership encompasses responsibility and the deliberation of the sustainability and appropriateness of the methods and results in question. While the choice to abandon nuclear power does bring the decision-making process closer to the common people, ordinary citizens will need to spend more time deliberating over the types of energy available and the costs they are willing to pay.

People make mistakes. Thus any social system must include the build-in possibility of learning and making adjustments. The scope of adjustment or even reversal is another name for resilience. The experience of 3/11 imposed numerous lessons, ranging in scope from the role of mutual help at the community level, energy supply at the national level, to the very definition of well-being at the humanitarian level. But it must also be remembered that major disasters of similar magnitude have also occurred in the past. The prime question for us is to determine what lessons we have learned from these occurrences, and how that knowledge has been applied in practice. Perhaps one of the major tasks of social and behavior sciences is not so much to deliver new theories or discover innovation but simply to remember lessons of the past and to devise mechanisms for their modification if and when the need arises. In this context, the role of social and behavioral sciences is to work with the people towards creating a vision of 'things otherwise', i.e., going beyond the current system's narrow emphasis on maximizing cost-benefit ratios, in order to question the very foundation of such a system.

Resilience from Memories

Unlike the people in Asia during the great Sumatra earthquake, many residents of the Japan's northeastern coastal line had had some knowledge of these periodic natural catastrophes. It could almost be speculated that people, faced with these natural uncertainties, would have developed some type of unique coping mechanism or resilience. This is exactly the point that Terada Torahiko raised 90 years ago in connection with the 1933 tsunami. By deploring the forgetfulness of people who had failed to apply the lessons from the great tsunami of 1896, he investigates human nature in the following way:

> A tsunami hit the Pacific coast of northeastern Japan. The waves swept away every small city and village on the coast and took countless human lives and valuables. Being a natural phenomenon that has occurred so repeatedly, one would think that the residents of the affected regions would have long ago thought of some measures to prepare for it, and that they would have been able to prevent the disaster from happening.… That this is not quite the case, it seems, is the very human natural phenomenon of the human world. Having suffered from the tsunami, people in the beginning may move to higher places; however, over the next 5, 10, 15 or 20 years, the population most likely will move back to the lower lands (close to the shore). Thus, another fateful day quietly approaches them.

Whatever 'lessons' contemporaries may highlight, many of these will be forgotten in the long run and what tends to remain is the public's overconfident faith in institutions and technology. It was only after the disaster that many of the ancestral stones that had been inscribed by past generations to warn people about tsunamis were 'uncovered' and their message appreciated. Perhaps the most foundational resilience

is not how we design communities or infrastructure, but how we continue to talk about past disasters in order to retain fragile memories. One of the most powerful sources of resilience is, in fact, people's sense of belonging to their hometown and their determination to restore their lives.

Humans are not sufficiently rational or far-sighted enough to be able to completely avoid all future disasters. Disasters arrive unexpectedly, but so do their countermeasures. While it may sound unwise to rely on intangible resources that are usually hidden and scattered, it is these seemingly unimportant, untapped potentials that can turn out to be useful. This potential, when gauged by the principle of maximizing economic value, tends to be dismissed as causal or slack. Thus, there is reason to maintain an 'alternative', diverse space where a different, autonomous logic operates. Freedom that allows diversity to function when it is called for is what we should appreciate. The praise for decentralization and self-governance ultimately boils down to their value in allowing some degree of autonomy to survive, and not because self-determination has been eliminated for the sake of economic efficiency alone. This lesson was born not only from the 3/11 tragedy, but also from Japan's overall development policy of the past 50 years, a pattern that exacerbated the effects of the 3/11 tsunami.

Social Science and Civil Society

Abstract

This article gives an overview of key social science approaches to civil society. It addresses in turn civil society organizations, volunteering, and philanthropy. For each, it looks at how they are defined, their scope, how social science approaches the study of them, and how social policy has sought to encourage or coordinate them.

Introduction

Civil society refers to the range of organizations and activities which occur outside of the traditional economic binary of market and state. They comprise the activities of and which occur within those organizations variously called charities, not-for-profit organizations, NGOs, civil society organizations, and many more. The term civil society though is hardly less contested. In the United Kingdom, the Coalition Government quickly renamed the New Labour-founded *Office for the Third Sector* the *Office for Civil Society* (Hogg and Baines, 2011). This rejection of the term 'Third Sector' is indicative of the way in which how we refer to the sector is laden with political dimensions and sectional interests (Ridley-Duff and Bull, 2011).

Indeed the notion of seeing civil society organizations (CSOs) as a collective group of civil society organizations is, Haugh and Kitson (2007) argue, a relatively recent idea; prior to the 1978 Wolfenden report, the wide range of civil society organizations in the United Kingdom were considered to be parts of the various sectors – education, sport, social care – in which they operated. The legacy of this is that huge heterogeneity exists in the organizations that are considered to make up civil society (Halfpenny and Reid, 2002). Any term used to define such diverse organizations with diverse goals and diverse means of achieving them runs the distinct risk of excluding some types of organizations and overemphasizing the role of others (Alcock, 2010). The inherent weakness of any catch-all term for the sector is what led Kendall and Knapp (1995: 67) to describe it as a "loose and baggy monster."

This article looks at the three dimensions of civil society to which social science has paid the most attention: the nature of the voluntary sector, the volunteering which occurs within it, and the philanthropic donations which fund the work it does. It addresses these three items in turn, outlining what they are, giving an overview of their scope and scale and looking at how social policy approaches the study of them. In doing so, this paper outlines the social sciences' approach to civil society. While the data analyzed in this article is mostly concerned with the United Kingdom, much of it reflects wider patterns and themes, and where large discrepancies exist between nations this is noted.

Civil Society Organizations

What Are Civil Society Organizations?

Among CSOs exists enormous heterogeneity in terms of the work they do and the way they do it (Hardill and Baines, 2011). Organizations identifying as CSOs can include charities, cooperatives, social enterprises, infrastructure groups, and others (Hardill and Baines, 2011). Turner (2001) and Milligan and Fyfe (2005) note that what unites CSOs is that they promote opportunities for social participation, for reciprocity, and for local democratic involvement for their volunteers and service users. Kendall and Knapp (1995) propose that there are five different functions which CSOs may seek to fulfill:

- *Service providers*: CSOs which exist to provide a direct service to individuals or groups, or to provide information or support.
- *Mutual aid*: CSOs which engage in self-help and exchange around a common need or interest.
- *Pressure group*: CSOs may be involved in policy advocacy or organizing campaigns, to put pressure on decision makers.
- *Helping individuals*: CSOs which offer help on a case by case basis.
- *Resource coordinating*: CSOs which act as infrastructure groups, providing support, training, and contacts to other civil society organizations.

CSOs may have one or more of these functions, and similarly volunteers may engage in one or more of these areas (Rochester et al., 2012).

While CSOs fulfill a range of important roles in society, the services and support that they provide has also been criticized and the limitations of their work recognized. Salamon (1987) reflects on the shift from civil society provision to a state-organized welfare system and notes that this in part stemmed from a recognition of the inherent failures of civil society organizations. Salamon notes four main weaknesses in CSOs:

- *Particularism*: Giving to organizations is voluntary, so provision is greater for causes that more people support. Therefore, help is not universal but reflects the personal tastes of those with the resources to provide them.
- *Insufficiency*: As the next section shows (Mohan, 2011; Clifford, 2012), the geographical spread of CSOs is uneven. There is no guarantee that provision will be evenly spread or given where most needed.
- *Paternalism*: It is suggested that civil society support can create dependencies, whereby the recipient is at the mercy of the organization and its supporters. This power relationship has been criticized by scholars of historical British charity (Finlayson, 1990; Davis Smith, 1995) who argued that civil

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41061-5

society was often motivated by a desire to shape the working classes in the image of their masters.

- *Amateurism*: CSOs have been accused of being run amateurishly, a lack of paid professionals (despite many organizations having a number of paid staff) meaning that they are badly run.

These realizations of the weaknesses of CSOs, some more valid than others, have led to some CSOs being part of a mixed economy of welfare in which they work alongside public and private organizations to deliver services (Hogg and Baines, 2011). Others exist beyond what the state would normally deliver, and beyond what private organizations would see a profit in perusing.

Where They Are and What They Do

In the United Kingdom, the National Council for Voluntary Organisations estimates that there are over 162 000 active CSOs (NCVO, 2013). The majority of these (52%) are small organizations with annual incomes of under £10 000, no paid staff, and only a small number of volunteers (NCVO, 2013). Very few (under 3%) of the CSOs in the United Kingdom have an annual income of over a £1 000 000, but these organizations account for over three-quarters (78%) of voluntary sector income. This is what Milligan and Fyfe (2005) describe as a 'bifurcation' of civil society, with larger, and more corporatist organizations increasingly working with the state – and with state funds – to deliver public services. At the other end of the scale 'grass-roots' organizations, smaller in size but very much in the majority, continue to work in their local communities quite removed from any state subsidy or interaction (Hogg and Baines, 2011).

One of the voluntary sector failures that Salamon (1987) identifies is that the provision of CSOs is unevenly spatially distributed, and that as such CSOs cannot be relied on to cope with all of the social problems present in modern industrial societies. Certainly, the geographical distribution of formally constituted CSOs in the United Kingdom is uneven. There are over 2.5 times as many formal CSOs working at the neighborhood scale in the most prosperous areas of the United Kingdom compared within the most disadvantaged areas (Mohan, 2011; Clifford, 2012). This pattern is particularly the case for those CSOs which support cultural and leisure pursuits, which provide education and lifelong learning and which engage in general community activities. The relationship reverses – with more organizations in more deprived areas, for those CSOs which support economic well-being, training, and community cohesion (Clifford, 2012). CSOs in more deprived areas are more likely to be larger and more likely to be in receipt of public funding, while those in less deprived areas are likely to be smaller and to raise funds through philanthropic donations (Mohan, 2011; Clifford, 2012). There is also a rural–urban split in terms of the spread of CSOs in the United Kingdom, with rural areas having over 50% more CSOs than urban areas per 1000 people (NCVO, 2013).

CSOs also engage in a number of areas of work, pursuing a range of aims. The 2012 National Survey of Charities and Social Enterprises (Cabinet Office, 2010) found that the most common areas for organizations to work in the United Kingdom were education and lifelong learning (28% of organizations listing this as their main area of work), leisure (21%), health and well-being (17%), community development and mutual aid (17%), culture, arts, and music (13%), religious- and faith-based activities (13%), and in training (10%). CSOs differ not just in terms of what they do, but also in terms of the number of paid staff and volunteers they have. The majority of CSOs have no paid members of staff at all – they are run entirely by volunteer efforts – while only 10% of CSOs have more than 11 paid members of staff (Cabinet Office, 2010). From these figures, we can observe that 68% of CSOs in England in 2010 had fewer than 20 volunteers, while just 4% had more than 101 volunteers.

Social Policy and Civil Society Organizations

CSOs exist within a wider context of relations between the public and private sectors. In the United Kingdom, prior to the 1911 National Insurance Act, CSOs were for the most part wholly independent of the state, delivering services in fields in which the government made no provision (Hogg and Baines, 2011). Between the wars, CSOs and state institutions increasingly worked in partnership, with the National Council of Voluntary Organisations (NCVO) formed in 1919 (as the National Council of Social Services) with the aim of coordinating CSOs and developing their ties with the state (Davis Smith, 1995). The 1941 Beveridge Report proposed the creation of National Insurance and the National Health Service, but it also saw a key role for CSOs in healthcare and social welfare provision (Davis Smith, 1995; Alcock, 2010).

In the 1980s, governments on both sides of the Atlantic adopted the principles of reducing the role of the state and strengthening the role of the markets (Hogg and Baines, 2011). CSOs were central to this, with the contracting of work previously seen as the state's domain to CSOs, seeking to encourage, "innovative and entrepreneurial forms of service delivery" (Curtis, 2008: 227). In the 1990s, as the state contracted further still, CSOs became even more significant in the delivery of public services (Buckingham, 2009). Kendall (2000), though, fears that this account overplays CSOs' role during this period. His stance is consistent with the analysis that CSOs were more often safety net (Halfpenny and Reid, 2002; Haugh and Kitson, 2007).

In more recent years, CSOs have been mainstreamed in British policy making, though New Labour's Third Way and the Coalition Government's Big Society initiatives (Hogg and Baines, 2011). It should also be noted that while many CSOs have seen their relations with the state change significantly over time, others have continued to exist well away from the reach of the state.

Volunteering

What Is Volunteering?

Definitions of volunteering vary depending on the particular focus of a study, but there is broad consensus as to what a broad definition of volunteering might look like; tasks undertaken are unpaid (allowing for the payment of expenses), they aim to benefit individuals, groups, and communities other than, or in addition to, close relatives, and they are undertaken

through individuals' own free will (Hardill and Baines, 2011; Rochester et al., 2012). Within this broad framework, formal volunteering entails all of this diverse activity which occurs within an organizational setting. This includes volunteering done through groups, clubs, or organizations in the public, private, or voluntary sectors (Milligan and Fyfe, 2005; Rochester et al., 2012). It is distinct from informal volunteering, which involves volunteer help given to an individual, family, or informal group by an individual, family, or informal group, often on an ad hoc basis (Milligan and Fyfe, 2005; Rochester et al., 2012).

Who Volunteers?

A wide range of data are gathered regularly about who volunteers and what they do, across the globe. However, as Rochester et al. (2012) argue, the questions a data gatherer asks and the methodology they use all influence the results obtained and as such comparative work must be undertaken with caution. The Charities Aid Foundation's World Giving Index 2013 attempts to use the same methodology across the globe, and it cites Turkmenistan as the nation with the most regular volunteers, with 57% of citizens volunteering in a typical month. Sri Lanka is second with 46% volunteering each month, with the United States (45%), Myanmar and Philippines (both 43%), and Canada (42%) close behind.

In terms of who volunteers and what they do, robust cross-national data is in short supply, and the different methodological approaches in different national contexts (Rochester et al., 2012) makes comparing between different countries troublesome. In the United Kingdom, women consistently volunteer at higher rates than men, a pattern which a 1995 survey in Europe (Gaskin and Davis Smith, 1995) showed to also be the case in Belgium. However, in Denmark, Germany, Ireland, the Netherlands, and Sweden, men volunteered at a higher rate than women (Gaskin and Davis Smith, 1995).

In terms of what volunteers do, data from the United Kingdom suggest that volunteers are engaged across an extremely wide range of fields. Sport and exercise, hobby and social clubs, religious organizations, education organizations (including schools), health charities, and many more are all popular causes for formal volunteers (Cabinet Office, 2013). Across the wide range of CSOs, volunteers undertake a wide range of roles, from giving professional advice on a *pro bono* basis to undertaking manual work such as digging or cleaning (Low et al., 2007).

Why Do People Volunteer?

Much has been written about impulses to volunteer, much of it from psychology literature, and often using closed questions and quantitative methods to 'measure' reasons for engagement. Within social sciences, the realization that every volunteer's motivations are unique lead Rochester et al. (2012) to state that there are as many motivations as there are volunteers. A further problem is the gap between what volunteers say about what motivates them when asked and what they themselves think (Rochester et al., 2012). Nonetheless, there are some useful frameworks from social science which help us to understand why people volunteer.

Omoto and Snyder (2002) state that there are three stages of volunteering: antecedents, experience, and consequences, each of which exists at individual, organization, and community levels. Here, we are interested in the individual level, at which the three stages are as follows (Omoto and Snyder, 2002):

- *Antecedents*: This is what comes before decisions to volunteer and is formed of the prior experiences and events which shape an individual's pathway toward volunteering. Rooted in social experiences, antecedents include life events, available resources, identity, social expectations, and surrounding social support.
- *Experiences*: This refers to how volunteers experience their roles, and the satisfaction they derive from their volunteering. It is shaped by their relationship with the CSO they volunteer with, how they are supported by paid staff, and how they engage with other volunteers. From these experiences, volunteers derive differing levels of satisfaction.
- *Consequences*: These are the outcomes from volunteering, in terms of changes in what people think, know, and do. It concerns how volunteering affects self-identity, and how this helps build commitment to volunteering and to the CSO volunteered for. Consequences feed back into future experiences.

This framework embeds volunteers and their efforts within a community context, which influences the volunteer and the work they do (Omoto and Snyder, 2002). Musick and Wilson (2008) also place volunteering with a context of social relations, emphasizing the importance of being asked in decisions to volunteer.

Another way of understanding motivations to volunteer lies in the distinction between *philanthropy* and *mutual aid*. Philanthropic voluntary activities are said to be those, "where an individual or group offers services to others" (Finlayson, 1990: 184). Mutual aid concerns voluntary activity in which individuals or groups undertake volunteering for mutually beneficial reasons. This reciprocity need not be immediate or explicitly agreed, and may indeed be deferred over long periods, but it is integral to mutual volunteerism that there is an obligation and an expectation for reciprocation (Finlayson, 1990).

This binary between self-interested mutual aid and altruistically motivated philanthropy is rejected by Hardill et al. (2007), who argue that volunteering needs to be understood in the context of the individual's life, to move away from this divide. They propose instead four groups of volunteer impulse:

- *Giving alms*: These are volunteers who have, "… identified an unmet need and they want to make a difference" (Hardill et al., 2007: 405). Often these volunteers see themselves as helping people less fortunate than themselves. Such volunteering is, "… necessarily both self- and other-rewarding" (Hardill et al., 2007: 405).
- *Giving to each other*: These are volunteers who seek to help others with whom they perceive a shared issue, as a response to a problem they experience together.
- *Getting on*: These volunteers are seeking to develop "…skills and experience of value in labour market" (Hardill et al., 2007: 406) through undertaking voluntary work.

- *Getting by*: These are volunteers who, "… entered volunteering as a response to a milestone life event, and that it fills something missing or an emotional gap in life" (Hardill et al., 2007: 207).

Understanding philanthropy or mutual aid in isolation is therefore a fallacy; there is inevitable overlap between them and each volunteering decision draws upon a complex mix of these and other impulses, internal and external.

Social Policy and Volunteering

Volunteering exists within a wider policy context, and a number of public policy decisions have sought to increase engagement in volunteering. Rochester et al. (2012) note that it was under John Major's Conservative Government (1992–97) that public policy on volunteering first became joined up across government departments. Following this, New Labour engaged in a wide range of events, initiatives, and programs with the aim of encouraging volunteering. The Coalition Government also have a cross-government commitment to volunteering, in the form of the Big Society. Their Giving White Paper (Cabinet Office, 2010), which looks at the giving of both time and money – view volunteering as a form of giving. The Coalition's approach to volunteering and CSOs is far more 'soft-touch' than New Labour's, and as such direct programs or initiatives are far scarcer (Rochester et al., 2012).

Philanthropy

What Is Philanthropy?

Philanthropy, in its broadest sense, includes all voluntary action which is undertaken for the public good (Payton, 1988). Within this definition is both the giving of time, explored in the previous section, but more commonly the term is used to refer to the giving of money, which is explored here (Payton and Moody, 2008). Daly (2012) argues that the meaning of philanthropy has changed over time, and differs between different contexts. In arguing that philanthropy is an 'essentially contested concept,' Daly (2012) draws on Payton (1987) and Van Til (1990) to argue that the shear range of ways in which philanthropy is defined means that when we debate it, we differ in not just the meaning we attribute to it, but also in terms of the values and purposes we see it having.

When viewed through economic theory, the philanthropic giving of money to charity is illogical in extreme – homo economicus sees no utility maximization arising from giving his money away. So why do so many people give? Homo sociologicus, on the other hand, is a far more complex character, and as with sociological approaches to volunteering, when it comes to the study of the giving of money it is the social context which is key (Halfpenny, 1999). Andreoni (1990, 2006) suggests the 'warm glow theory' as a way of understanding why people freely give their resources to others – they do so in exchange for a warm feeling of having done something good. This theme of doing something good is echoed by Schervish's (1998) assertion that philanthropy as a social relation revolves around the moral value of *caritas*, of a love for others and their needs.

Social science approaches to philanthropy consider both the impact upon wider society and the impact upon the donor themselves, a tension which Frumpkin (2006) sees as involving an awkward balance between private interests and public needs. Veblen (1899) saw the act of giving as a conspicuous way in which donors show how much money they have, while Bourdieu (1984) conceptualized charitable support for artistic and cultural activities as a way in which donors can show off their cultural capital and exceptional taste. As such, Breeze (2012a) argues that acts of philanthropy are both an attempt by donors to shape and change the world around them, and a way in which those who give can change their own self-image and the way in which they are perceived (or hope they are perceived) by others.

Who Gives and To What Do They Give?

The practice of giving money to CSOs to spend on charitable causes is widespread across the world. In 24 countries, over half of the population give to charity in an average month, with Myanmar leading the way where 85% of citizens give each month (CAF, 2013). The United Kingdom comes in second globally, with 76% giving, while in the United States, Canada, The Netherlands, Australia, and New Zealand over 60% give in an average month. While all countries have some citizens who give regularly, it is not so widespread in a number of places – in 51 countries, the proportion giving is less than 20%, while in Georgia it is just 3% (CAF, 2013).

Data from both the United States (Andreoni, 2006) and the United Kingdom (NCVO/CAF, 2013) shows that people tend to give more with age, both in absolute terms and as a fraction of their income. The impact of gender is less marked, with Bekkers and Wiepking (2007) finding no significant differences between men and women's giving in the literature. Research from both sides of the Atlantic finds that those with more education tend to give more often and larger amounts than those with lower education (Andreoni, 2006; Low et al., 2007; Cabinet Office, 2013). In terms of the link between religion and giving of money, Bekkers and Wiepking (2007) find that almost every report on the link between religious attendance and philanthropic giving finds that those who attend regularly give more regularly and more often. Family impacts too – nearly every study which looks at the impact of marriage and having children finds that these increase the likelihood of giving and the amount given (Bekkers and Wiepking, 2007).

In terms of the causes people give to, religious causes dominate in the United States (Giving USA, 2013), while in the United Kingdom medical research and hospitals, children, and animals dominate year after year (NCVO/CAF, 2013). Differences in categories between the United States, the United Kingdom and other national contexts make comparisons difficult, but broadly speaking donors as a whole tend to support medical charities, children and animal charities, while major donors are more likely to support higher education institutions, arts and cultural organizations, and medical research (Breeze, 2013a).

Why Do People Give?

In their review of the literature on charitable giving, Bekkers and Wiepking (2007) identify eight mechanisms which have been identified as determining why individuals give to charity:

1. *Awareness of need*: Before they give, people have to become aware of a need for money to be given to that cause. This awareness can come about in a range of ways, including personal experience, charity advertising, news stories, or other ways.
2. *Solicitation*: A large proportion of donations are made because they are asked for – Bryant et al. (2003) find that 85% of donations were given following a request being made, while Bekkers (2005) finds that 86% of donations were made following a request.
3. *Costs and Benefits*: Giving costs money, and when this is made cheaper (e.g., through the Gift Aid tax program in the United Kingdom), then people are more inclined to give. Donating can also have tangible benefits, such as VIP access to events or areas not accessible to nondonors.
4. *Altruism*: People give to charity because they care about the work being done.
5. *Reputation*: This links back to Veblen and Bourdieu's ideas that giving can be used to improve an individual's social standing. Giving is seen as a good thing to do (mostly, although media portrayals in the United Kingdom would sometimes make you question this) and as such giving can help to improve a person's reputation among their peers.
6. *Psychological benefits*: Beyond the social benefits of giving, there are also psychological benefits, including boosts to self-image, producing positive moods, alleviating feelings of guilt, being a way of showing gratitude, and simply making one feel as though one is a good person.
7. *Values*: Donors give to organizations which reflect their own values, in the hope that they can make the world – or just the bit of the world they care about – a better place.
8. *Efficacy*: Donors want to feel as though they are making a difference to the cause(s) they support, and a feeling that their donation can make a difference is significant to giving decisions.

It should be stressed that for each act of giving, a range of different factors from across a number of these mechanisms may be in play, and that these will change for individuals over time.

Beyond looking at why individuals give to charity, Breeze (2013b) looks at how donors chose which charities to donate to. When deciding where to direct a charitable gift, donors base their decisions on four key areas:

- *Tastes*: Donors' own personal tastes are the most significant factor guiding where they direct their donations. As with the awareness of need and altruism identified by Bekkers and Wiepking (2007), Breeze (2013b) finds that donors support causes close to their hearts.
- *Experiences*: Each donor has their own personal history of experiences, on which they draw when making decisions where to donate. These may be based on childhood experiences, being touched by an illness or some other life event, and they change over the life course.
- *Perceptions of charity competence*: People want to give to charities which they perceive as competent, and where they can be confident that their donations will be used effectively.
- *Desire to have a personal impact*: Donors want to feel that their donation is making a difference to the work the charity does, hence often therefore explain what a donation of £50 or $100 can provide.

Again, for each donor the way in which they make these choices and negotiate these decisions is different, but Breeze's (2013b) heuristic offers a useful method of understanding how donors choose where to give.

Political Support for Philanthropy

Political support for philanthropy has in the United Kingdom been a feature of policy making since the 1980s, a period during which huge increases in private wealth occurred due to global capitalism, while simultaneously, as we have seen previously, the frontiers of the state were being rolled back (Pharoah, 2013). During this period, measures were introduced to stimulate giving, most significantly the Gift Aid tax relief scheme in 1990, enhanced in 2001 (Pharoah, 2013). The Coalition Government's support for giving continued, particular around their Big Society policy framework. However, governmental approaches to philanthropy are often, Breeze (2012b) argues, simplistic and underestimate the complexity of philanthropic decision making, as outlined earlier in this section. Instead, philanthropy is simplistically presented as a 'good thing,' the practicing of which will inevitably lead to stronger communities and better services. The qualities that philanthropy has, and the inherent weaknesses of civil society noted by Salamon (1987) mean that this easy acceptance of philanthropy as a good thing is potentially unhelpful.

Civil Society and Social Science

Historically and to the present day, CSOs and civil society actors have played crucial roles in funding and supporting social science research. Much of the initial growth of universities and research institutions, both secular and faith based, was organized and funded by civil society groups (Curti and Nash, 1965) and universities globally continue to receive significant philanthropic funding from alumni, foundations, and major donors (Breeze et al., 2011). Indeed, in the annual Million Dollar Donors (USA) and Million Pound Donors (UK) surveys, higher education institutions consistently emerge as the most common destination of major philanthropic donations (Breeze, 2013a; Coutts, 2013). Civil Society foundations and charitable organizations also fund social science in a number of other ways. Large funding bodies such as the Leverhulme Trust invest heavily in social science research, while charities invest in PhD researchers and in research projects and programs (Macmillan and Scott, 2003).

Civil Society has also often taken a lead in identifying areas for social science to explore and investigate. This is demonstrated by the pioneering campaign work of philanthropist criminal justice campaigner John Howard (1726–1790) and of the organization that takes his name, The Howard League for Penal Reform, formed in 1866, is the oldest penal reform organization in the world and played a significant role in the formation of the modern social science discipline of criminology (Morris, 1988). The experience that CSOs and those who work with them have of social issues feeds into social science research, a symbiotic relationship where research and civil society provision and campaigning mutually support each other.

Conclusion

This article has given an overview of key social science approaches to civil society. It has addressed in turn CSOs, volunteering, and philanthropy. For each, it has looked at how they are defined, their scope, how social science approaches the study of them, and how social policy has sought to encourage or coordinate them.

Abstract

Media is an integral part of the contemporary social world. As an object and subject of social science disciplines, media and mass media are defined, theorized, and approached in a multitude of ways depending on the discipline and question guiding the research. Mass media has a long history whose trajectory has made it a major factor in influencing and shaping society. The shape of media, and thus of society, is constituted by and reconstitutes the social and political contexts of any given temporal or social moment as it relates to the social systems and media infrastructure coinciding with it.

Social Sciences and the Media

Media as Institutions

Mass media refers to institutions that use technology to address large numbers of people. It is characterized by a one-way communication system between a single entity and a larger audience. Spoken or visual communication limits audiences to those physically present to see or hear it, making it difficult to reach a mass audience. The innovation of written language allowed communications to be kept in their original form, as well as to reach people who were not physically present at the time of their inception. The invention of the printing press allowed for the efficient (re)production of written content, making it possible for mass audiences to access written media. Media diffusion, although aided by the printing press, remained dependent on the spread of literacy.

The ability to print and produce media in large quantities using a printing press is commonly accepted as the first revolution of the mass media, but there have been further revolutions: the invention of radio, TV, and Internet Communications Technologies, also referred to as new media or digital communication. In contrast to theories of creative destruction (as suggested, e.g., by Joseph Schumpeter), the revolutions in mass media have added technologies to the mass media toolkit, rather than replace aging ones. Books were not abandoned with the dawn of radio, for example, nor has radio disappeared in the face of television, the digital revolution, and the Internet.

Upon examination of the waves of media innovations, it becomes clear that the addition of new revolutionary technologies is becoming more and more frequent; in other words, the development of technology over time is telescoping. The 1460s saw the spread of the use of the printing press across Europe; the mid-1800s witnessed the telegraph become widely used; film was becoming more accessible by the beginning of the 1900s, followed by radio gaining popularity in the 1920s. Television rose to prominence after WWII in the 1950s, and the 1970s saw the dawn of the personal computer. By the 1990s, people were surfing the World Wide Web in large numbers, but they did not stop reading books, as the success of online book vendors like Amazon demonstrates. However, the successful penetration of digital technology has changed the character of media fundamentally, as one-way communication from sender to audience was replaced by interactivity as the general mode of transmission.

Media as Infrastructure

Many theories and speculations have come along with the various technological revolutions of media. Marshall McLuhan (1911–1980), a prominent media theorist, argued that the medium of communication strongly influences the messages communicated through it. McLuhan's ideas represent a concept called technological determinism: a way of thinking that emphasizes the influence of technology on society's communication, rather than social processes. Foundations for technological determinism can be found in historical materialism, a theory initially developed by Karl Marx which posits that material conditions, including technology, are the primary influence on the organization of societies. Parallels to McLuhan's thinking are evident in Althusser's notions that discourse, and thus any expression of ideas through the use of language in media is constituted by the context in which it originates (Jorgensen and Phillips, 2002). A contrast to this way of thinking can be seen in Laclau and Mouffe's discourse theory, which asserts that language use (i.e., by the media) shapes our understanding of the world around us. Thus, the struggle to achieve power is the struggle to attach meaning and remove unwanted ambiguity from language (see Laclau and Mouffe, 1985). (For more on technological determinism and politics, see Hoff et al. (2000); Ong, 1982; or the work of Harold Innis or Marshall McLuhan.)

"Whatever we know about our society, or indeed about the world in which we live, we know through the mass media" (Luhmann, 2000: 1). This is the opening sentence of Niklas Luhmann's book *The Reality of the Mass Media*. If we accept Luhmann's idea, even in part, we accept the powerful role the media plays in shaping human society. This power intrigues social scientists and has led to large amounts of social scientific literature exploring the infrastructure of media as a tool for political, social, and economic power.

Media as Systems

Media and Power

Theories on the role of the media in society have a tendency to couple power and media, whether directly or indirectly. Michel Foucault (1980) links power and knowledge, asserting that power "forms knowledge [and] produces discourse." (119) Knowledge and discourse, if we refer back to Laclau and

Mouffe, or Luhmann, are inseparable from power and politics. Jürgen Habermas (1992) asserts that as media technologies grow and multiply, so does their propensity for being wielded as instruments of political power. "The public sphere, simultaneously pre-structured and dominated by the mass media, developed into an arena infiltrated by power in which, by means of topic selection and topical contributions, a battle is fought not only over influence, but over the control of communication flows that affect behavior while their strategic intentions are kept hidden as much as possible" (Habermas, 1992: 437). Pierre Bordieu and Habermas agree that media have experienced convergence with the economy, marketizing the arena of political power within media practices. The power of the media is thus constituted in the ability to determine views of the world through topic selection, or, as Entman (1993, 2007) refers to it, framing. Framing happens when media "select some aspects of a perceived reality and make them more salient … in such a way as to promote a particular problem definition, causal interpretation, moral evaluation, and/or treatment recommendation" (Entman, 1993: 52), thereby promoting a certain interpretation. Media frames serve to set a political agenda, determining which problems become salient for the public and receive political attention (Entman, 2007: 164).

Media and the Modern State

With mass media securely bundled to politics and power (Mancini and Swanson, 1996: 11), social scientists have turned to examining the role the media plays in politics of the modern state. Hallin and Mancini, in their seminal work *Comparing Media Systems* (2004), assert that it is futile to try to understand the political system of a state without understanding the media, and vice versa. Voltmer (2012) notes that while the media and political systems are irreversibly intertwined, the "political system … ultimately has the power to make binding decisions and thus shapes the basic structure and functioning of the media system" (239). Media institutions are further linked to the state through the idea that nationhood and national identities are critical definers of the purviews that media institutions inhabit (Sparks, 2005: 37). Further work similarly emphasizes the crucial role media plays in any changes in political institutions (Coyne and Leeson, 2009; Schudson, 2002).

Media Systems and Contexts

Media is not an uniform idea, product, or set of actors. The role, output, goals, and impact of the media differ depending on their context. Hallin and Mancini (2004) undertook a major comparative study of media systems in the western world, creating three broad categories for an initial categorization. Although no country fits perfectly with any of the following models, Hallin and Mancini (2004) have provided the necessary guidelines and framework for considering the classification of media systems.

Important for appraisal of a media system are four dimensions:

- Media markets
- Political parallelism
- Journalistic professionalism
- State intervention.

These four dimensions "can be regarded as universally applicable tools for describing the dynamics of media and politics in different contexts: All media organizations have to generate revenues to produce their outputs; decide on whether or not to engage in alliances with social groups and, if so, which ones; internally agree on the rules of operation and the norms that set the standards for evaluating their outputs; and finally position themselves vis-à-vis the actors and institutions of political power" (Voltmer, 2012: 227).

Hallin and Mancini's (2004) use these four dimensions to categorize western media systems as follows: The Polarized Pluralist model is found predominantly in European Mediterranean states, and characterized by an elite orientation, significant parallelism between media outlets and political ideologies, and substantial state involvement in media. This contrasts with the horizontal orientation, corporatist alignment, and journalistic autonomy and professionalism of the Democratic Corporatist model, common in Northern and Central Europe. The third model is the Liberal model, predominant in the United States. This model is described as having a low degree of political and social parallelism, a media independent of state financing and regulation but subject to commercial pressures, and high journalistic professionalism. The Liberal model, often viewed as an information service, is commonly perceived as the dominant model of media system as globalizing tendencies proceed.

The study of Hallin and Mancini (2004) was criticized since their typology of media systems only accounts for Western Europe and North America. The authors reacted by editing a volume in which their categories are used to explore media systems: "Media Systems: Beyond the Western World" (Hallin and Mancini, 2012). This study demonstrates that in order to describe media systems in other regions of the world additional categories and models need to be included.

Media in Different Systems: Democracy, Autocracy, Dictatorship

The typology of media systems using Hallin and Mancini's framework is limited to national contexts which display the minimum tenets for democracy and is also rooted in western thought. "Like the Habermasian public, the Hallin-Mancini framework is predicated on bourgeois rationality and on assumptions and values that are not dominant within what might be an African model" (Hadland, 2012: 116). This is likely true to a greater or lesser extent for the rest of the world. (For more on specific critiques of Hallin and Mancini's model, see Hallin and Mancini, 2012.)

Further classifications of media types and systems have been published which apply to other regions; these also emphasize the connection between media and political systems. Ayish (2002), careful to describe his classifications as patterns rather than models to underline their dynamism (p. 152), identifies three categories for Arab Television media:

- Traditional Government Controlled
- Reformist Government Controlled
- Liberal Commercial.

Nisbet and Moehler (2005) similarly create categories for Sub-Saharan Africa, namely the following:

- Open Democratic
- Liberalized Democratic
- Liberalized Autocratic
- Repressed Autocratic
- Closed Autocratic.

These few examples (as well as others, see: Rugh, 1979; Curran and Park, 2000) draw upon some similar guidelines to those of Hallin and Mancini (2004), but also focus on other important dimensions such as the reproduction of the status quo, or support for change, which again stresses the idea that the media commonly functions as arena of power struggle.

Technological Change

Technological development very often brings about changes in media (options) and in the way people communicate. The more options (in terms of media) people have for communication, the greater the choice of a medium to fit the message. After all, politics is communication; messages will have different effects depending on the medium through which they are transferred, which means that with every new choice of medium, the complexity of communication and thus the complexity of the political arena increases.

In the past 50 years, two major technological developments have dramatically changed the way we communicate. The invention of television was an event that revolutionized the media landscape and impacted the way in which power struggles have taken place since. While literacy was a required prerequisite for consumption of media associated with the development of the printing press, television required only infrastructure (a television set, electricity, and a broadcaster) to reach mass audiences. In contexts where the infrastructure for television was present, the medium was adopted rapidly: In 1949, only 2.3% of US households had a television; by 1960, 87% of households had one (Proir, 2007: 59).

Television, with its possibilities for combining visual and audio inputs, quickly became a favorite among the spectrum of media options. With the rise of television, there was a sharp rise in consumption of news and other contents which were extended to less educated audiences who were less apt to read newspapers (Prior, 2007: 56). The inclusive and accessible format of television changed communication; not only well-organized content but also the visual presentation thereof became important. An oft-cited confirmation of the prevalence of television in political power struggles is the 1960 television debate between US-presidential candidates Nixon and Kennedy. A well-tanned, made-up, visually presentable Kennedy triumphed over the paler, sickly looking Nixon whose campaign had not grasped the magnitude importance of the event (Schroeder, 2008). Television allowed the media to focus more efficiently on the people who represented various interests in political debates (Mancini and Swanson, 1996: 11), making personal appeal and connection between political actors and their audiences an essential factor.

Until the turn of the twenty-first century, television had become the prime and most powerful medium in political communication: the ubiquity of TV not only changed the focus (as demonstrated with the Kennedy–Nixon debate) but also the context of communication. Television is a more expensive medium than print or radio; actors who vie for power via this medium can expect to reap rewards, but also to pay a handsome price. Thus, the development of television is seen to increase the role of money in political communication and debates (Mancini and Swanson, 1996) at the cost of rational debates.

'New' Media

The latest wave we were able to observe is the rise of new media. At the turn of the twenty-first century, many social scientists were hopeful that the introduction of digital media would reverse the long-term declines in civic and political engagement. The introduction of digital media changed the cost and structure of communication by increasing the speed with which information could be gathered, and growing the overall volume of information people could access (Bimber, 2003). It also created new opportunities for targeted, two-way communication across space and time. With an estimated 96% of the world population subscribing to mobile-cellular services, and 41% of households worldwide connected to the Internet (Estimated by the International Telecommunication Union, retrieved 22 January 2014 from www.itu.int.), the face of communication has changed.

As a result, cyber-optimists believe that digital media use will strengthen democracy by enhancing two-way, targeted communication between parties and citizens (Dertouzos, 1997; Grossman, 1995; Negroponte, 1995). However, research has emphasized that the outreach of political actors through new media has enhanced selectivity. Thus, political parties made little effort to include new or undecided groups. Instead, they continued to target their communication toward party members and partisans and used their online presence to strengthen ties with already strong supporters. Parties also made little use of the interactive features digital media offers. Instead of moving to a more democratic, horizontal style of interactive communication, political actors strengthened their control over the flow of political communication from the elites to the voters (Bimber and Davis, 2003; Gibson et al., 2003; Gibson & Ward, 1998; Jackson & Lilleker, 2009).

Unlike the Web 1.0 environment, the Web 2.0 environment blurs the boundaries between the user and the producer, in a way that any user can produce content by posting comments, uploading videos, and sharing information. Although the term 'Web 2.0' was coined in 2004 (O'Reilly, 2005), the shift from Web 1.0 to Web 2.0 was characterized by a rather gradual change from the ability to consume content to the ability to coproduce content (Cormode and Krishnamurthy, 2008). The result is a change in the way information is shared and produced. Moreover, this has caused optimism for a more inclusive and more democratic pattern of communication: "The democratic nature of Web 2.0 is exemplified by creations of large number of niche groups (collections of friends) who can exchange content of any kind (text, audio, video) and tag,

comment, and link to both intra–group and extra–group 'pages'" (Cormode and Krishnamurthy 2008: n.p.). The potentials of this form of communication open up the communication for political outsiders and challenges from civil society who have had little chances to access public and political debate under the conditions of traditional mass media.

The introduction of new social and participatory media in the mid-2000s has increased the democratic potential of political communication by lowering the barriers for participation and inaugurating new action repertoires of political mobilization. Hence, Bennett and Segerberg (2012) argue that mobilization takes new forms of personalized 'connective action' which complement the traditional modes of social movement activity and protest politics. The ability for individuals and groups to coproduce content and immediately access political debate via Internet and mobile communication challenged the gate-keeping role of traditional mass media and party elites to fully control communication as a top–down process of communication. Thus, the Internet revolution and the advent of Web 2.0 contribute to the emergence of new 'hybrid media systems' (Chadwick, 2013) consisting of traditional political actors like parties and governments, traditional media, and Internet activists who are entangled in extremely fast and dynamics of political agenda setting and framing.

Media Studied by Various Social Science Disciplines

While the current approach to mass media differs depending on the discipline, there exists a significant amount of cross-fertilization in the study of the media between the social scientific disciplines. Lazarsfeld/Bereleson/Gaudet's study entitled: *Voters Choice. How People Make up Their Mind in a Presidential Campaign* is a prime example of media and communication drawn on by all social science disciplines.

The strong link between media and politics (as emphasized above) commits political science to take an interest in media, and communication science to take an interest in the study of politics. Moreover, as politics is the struggle for influence (power) through communication, the mass media's functions have become an irreplaceable factor in achieving political ends. Once a polity has reached a size where it is no longer possible to include all citizens directly in the political process, messages must be produced and addressed to large numbers of unspecified recipients. In this way, politics takes place largely in the purview of the mass media, making the study of communication inseparable from the study of politics.

Political Science investigates media on three levels:

- macro
- meso
- micro.

At the macro level, agenda setting via the mass media is examined. The meso level of investigation includes the effects of media on the intermediary system. How do parties, interest groups, and NGOs communicate? What effect do the media have on these organizations (macro and meso levels are also closely related to sociological study of mass media)? The examination of voting behavior of individuals constitutes the micro level, where there is also significant overlap with psychology. The subfield of campaign communication developed around 1990 at the intersection of party research, electoral research, and communication and media research. An important field of study in political science pertains to the mass media's effect on political campaigns: do they matter (Farrell and Schmitt-Beck, 2002)? From the field of electoral research, the emphasis lies on changes in voting behavior as caused by campaigns.

While research in political science focuses on mass media and communication within the framework of political institutions and processes, communication sciences takes a broader perspective and goes beyond the framework of political decision making and governance. Though studying political communication as one subfield, it opens up the perspective by asking how flows of information and other forms of messages (like entertainment) are created in media organizations, media businesses and markets and journalism and media cultures (McQuail, 1983). Social scientists within the field of communication investigate the creation of media reality as an integral part of social reality and study the media as institutions that select and produce messages for public debate in society at large. Communication scholars ask how processes of communication influence are shaped by media practices and how they influence cultures, identities, and public sphere.

Psychology's line of inquiry focuses on the effects of the media on the individual in the paradigm of persuasive communication. The history of psychological thought on media can be divided into four major phases which have connections to the historical development of mass communication mediums. The first is the focus on media as propaganda, with strong effects on the individual. This phase is associated with the rise of radio and can be exemplified with the 1938 radio broadcast of the H. G. Wells' *The War of the Worlds*, which instigated fear and panic among many listeners who perceived the story to be reality. Psychology then played down the effects of the media on the individual in the second phase, a paradigm shift that was in part brought on by Lazarfeld et al. (1948) study, which challenged the idea of profound media effects on the individual and society, suggesting that individuals played an important role in the formation of each other's perspectives. The third phase coincided with the spread of television and suggested again that individuals were powerfully influenced by the media, which could influence what people think by influencing what they think about. The fourth phase is characterized by a plurality of models of thinking about the individual and media, including gratification, selectivity, and reception theories. At the same time, contemporary debate in media effects research has also started to question whether the traditional psychological paradigm of persuasive communication is still adequate to account for the impact of media under the new conditions of media environments, communication modes, and messages (Bennett and Iyengar, 2008).

Sociological approaches to media include elements from political and psychological theories, but the focus is on how media affects society. Lazarsfeld, for example, is seen as a sociologist, as are Habermas, Luhmann, and others. Sociology concerns itself with media's role in power struggles (as is the subject of political science), looking at how these come to be

and relate to one another. The public sphere (see Habermas, 1992) or public spheres are the arenas where mass media and other communication create consent, that is, normalize and disperse ideas as a basis for action. Sociologists also look at how media processes are formed. Thus, there is an emphasis on language use and meaning in the social world. A basic sociological question driving media research is how media contributes to societal change or reinforcement of the status quo.

Conclusion

Media, especially mass media, can determine our understanding of societies as well as society's understanding of itself. Power struggles, regardless of the configuration of social groups partaking of these struggles, take place largely through acts of communication. The extent to which media is therefore involved in social struggle renders it a strategic role as a power broker. This is the essence of the interest of the social sciences in studying media: understanding how societies come to be arranged the way they are, as well as to gain insight into past, present, and future changes in societal arrangements. Observing and analyzing changes in communication patterns, methods of communication, and the instrumentalization of media thus form an important part of the social scientific quest to understand, analyze, and evaluate society.

Social Science and Universities

Sheldon Rothblatt, University of California Berkeley, Berkeley, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although unrecognizable by their present names, the social sciences have been taught at universities from their founding. At medieval universities, they were tucked away in language or mathematical 'faculties' governed by the theories of Aristotle and his Jewish and Arabic commentators. Finding medieval approaches to knowledge constricting and insufficiently useful, critics and governments created alternative institutions: academies, technical and vocational schools, and specialized professional programs. These institutions varied by period and country. In the long run, however, universities proved to be the most adaptive and resilient, creating different structures for new specialties and new modes of teaching. The definition of an academic career changed to allow for greater disciplinary specialization. In the social sciences, special credit must be given to the Scottish universities of the eighteenth century for pioneering approaches to economics, political science, sociology, psychology, and history. From the nineteenth century onward, industrialism, urbanism, and global wars produced greater demands for pure and applied 'research' (regarded as a German innovation) and problem-solving methods. The digital revolution of the twentieth century has had similar consequences. Today, some social science activity takes place within governmental and private sectors. However, although the boundaries between institutions are more fluid than ever, the university remains the primary location for the fundamental advancement of all forms of knowledge.

Since they first appeared in the twelfth century, universities have been the main, if not exclusive setting for the development of the social sciences. No two universities are, or have ever been, alike, but all possess common features. A division of intellectual labor is foremost. The curriculum, composed of building blocks of knowledge called 'disciplines,' is organized into multiple teaching, training, or research structures called variously (depending upon time, place, and national language) 'faculties' (the oldest), 'institutes,' 'laboratories,' 'departments,' 'schools,' 'boards of studies,' 'colleges' (which can be freestanding), or, more recently, 'programs,' 'organized research units,' or 'centers.'

The Problem of Knowledge

Knowledge and understanding are acquired through classification and specialization. The absence of a universal measure or definition of 'the disciplines' does not alter the elementary cognitive principle that unclassified information is relatively useless. According to the philosopher and logician Alfred North Whitehead, specialism is the 'natural' path to meaning, which underlies all civilizations. Increasing specialism is a salient feature of modern life, an indispensable requirement for scientific investigation, intellectual discovery, and problem solving.

Institutionalizing Knowledge

Disciplinary specialization affects the primary internal structure of universities and their systems of teaching, research, funding, staffing, and even the arrangement of buildings and spaces. Specialties seek what some scholars call 'autonomy,' or control over their own destinies. Accordingly, specialties desire institutional guarantees of disciplinary self-regulation. But the opposite is equally true. The institutional forms themselves influence the content, development, and application of academic specialties. In turn, the missions of educational institutions such as universities are affected by outside pressures generated by governments, the judiciary, religious institutions, the professions, public opinion, the media, and, increasingly, the commercial demands of industrial or high-technology economies. The modern 'nation-state' has been an important element in the formation of all contemporary disciplines but particularly in the natural and social sciences. The relationship between the social sciences, their host institutions, and all other disciplines, as well as civil society and government, is consequently complex, unstable, and unpredictable. The rate of knowledge change and production is more rapid, however, in some historical periods more than others. The resulting disjunctions between the generation and absorption of knowledge can produce social consequences.

The Organization of Knowledge in the Medieval University

During the Middle Ages, university disciplines were incorporated into large divisions known as 'faculties.' Some faculties, as at Paris, were quasi-independent corporations within a single university, while others were less settled in their administration. 'Nations,' or houses for students from European regions were homes away from homes. They became subadministrative and teaching units with separate identities, as were colleges. The 'inferior' (or arts) faculty, with its broad divisions into language and mathematical studies, was a preparatory program for the 'superior' or 'higher faculties' in which the three great professional training programs were located – medicine, law (canon or civil), and theology.

The inferior faculty consisted of disciplines that contributed to the foundations of a general education. The seven liberal arts, inherited from Rome, were divided into two other general classifications. One was the language-based trivium – logic, grammar, and rhetoric. The second was the mathematically

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41064-0

based quadrivium – music, astronomy, geometry, and arithmetic.

The basic organization of knowledge in the arts and sciences teaching divisions was rendered more complicated by the teaching of the 'three philosophies' – natural, moral, and metaphysical – which were also derived from ancient classical sources. The analytical methods, as well as the substance of the philosophies, informed and interpenetrated all faculties and disciplines in a process of knowledge generation and debate that produced gradual and continuous revisions in the curriculum.

The Relationship of Disciplines to One Another

The disciplinary taxonomy does not by itself adequately explain the uses or content of disciplines. The study of literature, for example, of texts such as Virgil's Aeneid, was included within grammar and thereby subordinated to the teaching of syntax.

Architecture could be found within the quadrivium, allied to the mathematical sciences. Rhetoric was a particularly elusive discipline. In some universities (or periods), it was subservient to grammar or logic and often limited to letter writing and religious preaching, but in other circumstances it was an important ingredient in the training of lawyers and public servants. The character of political science (based initially on Aristotle's *Politics*, translated into Latin in the mid-thirteenth century) changed significantly when it was later associated with law and employed in the task of building bureaucratic central governments to replace medieval feudalities. Religious questions regarding the existence of the soul were not confined to the faculty of theology but were debated within logic, using such assigned texts as Cicero's or Aristotle's *Topics*.

Science, in the modern sense of the study of nature, and medicine were part of metaphysics, where various methods and subjects commingled. In a scribal-based and/or oral academic culture dominated by the writings of a relatively few classical authorities, with their Arabic, Jewish, and scholastic glossators and commentators, disciplinary crossover was readily achieved. The need to focus attention on a limited number of issues, notably those related to the spread and administrative growth of the universal Church of Rome or the fiscal and legal problems of princely and imperial courts, contributed to a unity of academic purpose.

Yet the principal differences of knowledge production and acquisition between the medieval and modern universities should not be exaggerated. Disciplines absorb concepts and methods from one another (in other words, the contents of disciplines overlap) and the direction of scientific investigation is influenced by the uses to which knowledge is put. The capacity of a discipline to describe its own trajectory is constrained (positively or negatively) by the faculty or disciplines (or professional associations) to which it might defer.

Today's universities have characteristics similar to earlier universities. The placement of contemporary disciplines like sociology, political science, ethical philosophy, or even cultural anthropology within a school of law determines the approaches and problems that receive primary attention. The study of economics, when situated within business schools, inclines more toward problem solving than toward the laws or principles underlying economic behavior. Historical inquiry, when located within departments of economics, political science, policy studies, music, or education, becomes the study of the evolution of those fields, or is oriented toward questions of interest to the supporting departments.

Anthropologists whose appointments lie within medical schools and hospitals address issues arising from the treatment and care of patients, as do ethical philosophers, psychologists, or social workers in the same environment. Architecture is affected differentially when associated with engineering, schools of urban planning, colleges of the environment, schools of design, or the liberal arts. The study of music in research universities favors composition, musicology, and the history of music more than performance. The examples of disciplinary plasticity and shifting allegiances are endless.

Continuities and Discontinuities in Knowledge Acquisition

The medieval university was not ideologically designed for intellectual discovery but for the dissemination of knowledge. Nevertheless, significant knowledge growth and development transpired, although often unrecognized by practitioners or credited by polemicists. Change was advanced by the normal process of argument, by the discovery of new texts, by the reinterpretation of older sources, by the evaluation of existing systems of logic and proof, by theological controversies such as the Great Schism of the fourteenth century, and by issues concerning ecclesiastical reform eventually culminating in the Protestant heresies.

One essential difference between medieval and modern universities is the higher degree of self-conscious disciplinary promotion in the modern university, as driven by modern professional and external imperatives. Another important difference is the greater amount of ambiguity and relativism tolerated by modern cultures.

Scholasticism and Humanism

The period termed the 'Renaissance' (now usually called the 'early modern' period) or 'rebirth' of classical learning, beginning with fifteenth-century Italy and spreading northward in Europe in the centuries following, has long occupied a central place in discussions concerning the differentiation of disciplines and the arrival of 'modern' conceptions of learning. Historians conventionally divide the learned into two groups: the medieval schoolmen and the early modern humanists. Three issues separated the two groups. The first was the type and variety of classical sources later available when the Greek Byzantine Empire collapsed in Asia Minor. Authors and texts unknown or known only through hearsay were brought into Western Europe. Because sources could now be compared, an interest in variorum texts and in the detection of forgeries grew. Historical criticism, whose place was hitherto minimal, developed as a cardinal feature of early modern scholarship and was applied relentlessly to canonical texts and the dogmatic foundations of Western Christianity. A second issue concerned the role of observation and experiment in the conduct of scientific

work. Humanists and practitioners of the 'new learning' charged that inductive reasoning was neglected in favor of deductive systems of logic derived from Aristotle and his commentators. A third issue was the purpose of the university itself. Detractors alleged that the medieval university was isolated from practical affairs, its members preoccupied with abstract knowledge and shopworn or irrelevant ideas. A corollary point involved personal style. Humanists stressed public speaking, appearance, and the *vita activa*, being interested in careers at the courts of state-building aristocracies in an age of conspicuous political symbols and ceremonies. They contrasted the philosopher-statesman style with the torpid and pedantic manner of university teachers.

Stereotypes, however plausible, are notoriously dangerous, especially when shaped by polemical intent. Not all humanists were outside the university system. Many remained within, attempting, with success, to alter scholastic habits. Some scientists – Galileo is the archetype – borrowed heavily from scholastic methods of interrogating nature and were not as dependent on experiment and observation as they, or encomiasts claimed. And some humanists, in their zeal to attract the patronage of rulers, became hired propagandists, sacrificing their integrity as scholars to hypocrisy and superficial elegance. Furthermore, whatever directions humanistic scholarship took, it is now evident that the world of new learning was first framed within the intellectual structures and methods created by the medieval universities.

Alternatives to Universities

Nevertheless, criticisms of the university as a hidebound, antiquated system of teaching were convincing enough to result in the introduction of different institutional forms and new sources of funding in which innovation, particularly of an applied nature, received a more immediate reception. Even as early as the fifteenth century, the teaching of the common law in England was given a home in vocational institutions designated 'inns of court,' leaving Oxford and Cambridge universities with the teaching of canon law, Roman law, and jurisprudence. In the following centuries, academies, botanical gardens, royal libraries, observatories, museums, military schools, and new colleges were established outside university systems. The Jesuit order, founded in the sixteenth century, was and remained active in educational work. In France in the course of the eighteenth century, the state's need for experts resulted in the creation of specialized engineering schools, starting with the *École des Ponts et Chaussées* in 1747. The Jacobins of the French Revolution adopted this form for their own instrumental purposes. Their *École Polytechnique* of the 1790s was followed in the next century by other *grandes écoles*, institutions of high quality whose mission was to train specialists for appointments in government, industry, engineering occupations, or education. At the same time, the French university system was dismantled by Napoleon as irrelevant to the tasks of a revolutionary and secular society. That system was only gradually rebuilt but never attained the prestige of the leading specialized schools. Only recently has the university acquired a few of the research functions typical of universities in other countries, high-level research in France being normally assigned to a separate system.

The French *grandes écoles* are unique institutions in their patterns of student selection, purpose, and prestige. They are also unique because their prestige is not based on a research mission as in other countries (although now several research functions have been added). Few educational institutions anywhere have equivalent elite connections to the government, bureaucracy, industry, and leading professions. However, other countries have attempted to emulate some aspects of the French engineering model, most notably in the establishment of upper level polytechnical establishments in European capitals such as London, Berlin, Vienna, Stockholm, and Copenhagen, and in US cities such as Cambridge, Massachusetts, and Pasadena, California. Many of these have been evolving toward a university form. Relevant social science departments, foreign language teaching, and, in some cases, humanities courses were added, especially in the twentieth century.

But a second influence is the German technical university as it evolved in the nineteenth century. Also in Germany and Austria, other specialized universities were created: *Wirtschaftsuniversitäten*, for example – institutions where disciplines could be grouped and united with a focus on economic problems. In the United Kingdom, regional universities and university colleges were established, combining applied with liberal arts studies with special attention to the economic or social problems of their regions. Most of these universities later evolved into full-scale research universities.

Medical schools and hospitals, freestanding or associated with universities, became umbrella or 'incubator' institutions for an astonishing range of clinical and scientific specialties. Also in the nineteenth century, geodetic surveys and sponsored explorations supported certain kinds of limited intellectual activity. Although professional education as contained in the 'superior faculties' was the featured curriculum of the medieval university, and especially law in the later centuries, the admission of other forms of vocational or occupational training was never guaranteed. Law, medicine, and theology were acceptable because they suited the needs of urban societies in which religion and secular life interpenetrated. Vocational latecomers had to fight for entry. Rivals for income and teaching appointments and for students, space, and a role in governance, they represented the interests of outsiders. Hence, it was that newer professionalizing occupations of the later centuries, especially the nineteenth, such as engineering, commercial studies, school teaching, public administration, and social work, were associated with separate schools where they might develop an applied mission according to their own rules and methods. Several occupations – notably architecture, accounting, and some legal and medical activities – were controlled by practitioners recruiting through guild apprenticeship methods. But guild and academic forms of education are not necessarily incompatible. The academic profession itself is the supreme example of guild-directed education, controlling staff appointments and curricula.

Early twenty-first century universities tend to be comprehensive. Subjects or emphases once deemed unacceptable to universities built on the German research model or influenced by it are now more likely to be welcome. New recruits to the university community are normally expected to conform to its prevailing styles of intellectual achievement. However, the rapidly increasing fragmentation of the knowledge base evident

everywhere, along with market discipline and government policy, suggests that universities today are less able than predecessors to impose uniform standards of work or a common scholarly ethos on their numerous departments, laboratories, and programs of instruction.

The Transformation of the University

Applied and experimental science owed more to medieval systems of logic and natural philosophy than critics granted. Yet there was indeed a 'scientific revolution' of the seventeenth century that transformed the medieval worldview, produced a materialist conception of the cosmos, departures in physiology, and eventually the treatment of disease, and revised theological speculation concerning human understanding and potential. Mathematical measurement developed as a formidable scientific tool; for despite the medieval quadrivium with its mathematical base, the acceptance of Aristotle's physics by the schoolmen had produced a science that was heavily qualitative and metaphysical in character. Scientific instruments such as the microscope and the telescope, and later the Leyden jar, greatly enhanced the scope of intellectual achievement. Sophisticated machines have continued to be indispensable for science (and certain fields of social science), and never more than in the early twenty-first century.

The 'Knowledge Revolution' of the Nineteenth Century

Historical criticism, the development of the laboratory, and new systems of biological classification underlay the eventual adoption of a research ethic that completely reoriented the pantheon of disciplines inherited from the past.

Teaching and professional training were the two educational missions of the medieval university. Now there was a third, to be called 'research.' The ideas that knowledge could be created, that discovery was an aim of all scholarship, and that the new was preferable to the old were revolutionary assumptions that profoundly affected all educational institutions, and especially universities. The research spirit, while commencing in the scientific revolution and noticeable here and there in later Enlightenment Scottish, German, Dutch, or Swedish universities, did not dominate university culture itself until the nineteenth century. Historically, it is most closely associated with the German university model.

The general acceptance of an academic culture oriented toward original inquiry gave enormous impetus to the establishment of new or subdisciplinary fields. Pressures for the autonomous representation of those fields within universities increased. But two lasting versions of a research ethic emerged: one advocating discovery as an end in itself, the other advocating the use of research results to solve social, economic, or political problems, or to serve the needs of a democratic, consumer society. Proponents of the first feared that applied research funded mainly from commercial sources or results-minded governments would transfer direct and certainly indirect control over discipline formation and knowledge production to agencies outside the universities. 'Pure' research would suffer.

Advocates of the second noted the disappearance of any useful distinction between 'pure' and 'applied' knowledge in the age of high technology. In any case, contemporary society, they maintain, requires applied knowledge as a condition of survival and prosperity. Arguments remain intense, and the available evidence suggests that both sides have a case.

The Place and Influence of the Social Sciences within Universities

As noted, the 'social sciences' were embedded in the scholastic arts curriculum. The bureaucratizing states of the early modern period found a place for some forms of applied social science, notably *Kameralwissenschaft*, within the law faculties. The humanists, however, strengthened belles lettres within the faculty of arts (later, in the German university, to be called the faculty of philosophy). Accordingly, the maturation of the academic social sciences was a slow, two-stage affair. First came new methodologies for the study of social change and process developed by thinkers both inside and outside universities. Second was the emancipation of social science from domination by arts and professional curricula. Later Enlightenment Scottish university historians and philosophers were especially important in providing new insights into the evolution of society and culture. The 'science of man,' the disciplines of 'conjectural history' economics, political science, anthropology, sociology, and psychology are lasting Scottish contributions. Nineteenth-century French intellectuals such as the St. Simonians and Auguste Comte developed some of these beginnings into an overarching scheme of human development based on the 'march of mind,' the progress from primitive religion through metaphysics to 'positive science.' While the separation of subjects such as sociology, anthropology, economics, or psychology from such parent fields as law, history, religion, and philosophy was a nineteenth-century development, the flowering of social science as a full-fledged set of university disciplines belonged to the twentieth century. The timing was not accidental. A focus on the comparative, normative (and deviant) behavior of groups, communities, and classes; on the functioning of institutions such as schools, bureaucracies, professions, religious organizations, trade unions, industrial firms, and family structures; and on the nature of belief and value systems of societies reflected the dominant features and problems of modern society with its mobile, urban, plural populations, and global reach.

Besides concentrating on issues and problems not conventionally incorporated into the inherited model of a university, the social science disciplines claimed the prestige gained by the physical sciences. As in the natural order, the human or social order could also be explained by scientific laws. And, although in time some of the rigor and promise of words such as 'scientific laws' would be mitigated and exchanged for softer terms such as 'patterns' or 'regularities,' the claim to scientific objectivity served as a major legitimizing strategy. It was also the basis for an instrumental approach to the resolution of social problems and the means by which the social sciences secured access to external funding sources.

The number of social science disciplines and the different strategies pursued by social scientists to become citizens of the republics of letters and science in varying national contexts is

a highly complex story. Yet some insight into the issues may be gained from a cursory look at the history of the London School of Economics and Political Science (LSE), founded in 1895 by socialists and left-wing liberals on the model of the *École Libre des Sciences Politiques* in Paris (the LSE was later incorporated into the federal structure of the University of London).

Two issues confronted the founders. The first was the independence of the LSE, solved initially by the creation of a wholly new establishment where the disciplines could function on their own terms. This conforms to the pattern indicated earlier, where alternative institutions provide the means of disciplinary entry into the knowledge universe. The second issue concerned the LSE's primary mission, and here the founders disagreed on basic aims and methods. Should the institution's mission be applied or scholarly? Should attention be focused mainly on metropolitan regions such as London or spread more widely? Were ideological commitments to social amelioration compatible with standards of objective research? These differences of purpose have never been completely resolved within the LSE's academic divisions.

Indeed, the differences cannot be resolved since they are inherent in the history of the social science subdisciplines. The structural flexibility of the modern research university has provided a practical solution. The applied social sciences have found homes in the professional schools, a number of which – social work, urban studies, education, public policy, and perhaps now journalism and media studies – are in fact based on the social sciences. But law, medicine, public health, and architecture all have room for social science subjects and methods. Elsewhere in the university, the 'autonomous' social sciences are separated into distinct disciplines according to the history of each. They are located in departments within 'colleges of letters and science' (the typical US case), traditional arts faculties, or new faculties of social science (in some European universities). They are also to be found in crossover and multidisciplinary programs and research units.

Ideas, concepts, and problem-solving methods developed by the social sciences are now commonplace elements of any university curriculum. Historical research is greatly influenced by psychology, anthropology, economics, sociology, statistics, and political science, but history, as a 'universal recipient,' has often if not invariably demonstrated intellectual flexibility. Yet literary studies have also become social scientific as, inter alia, critics incorporate interpretations derived from the sociology of class relationships, the psychology of the individual, and the anthropologist's interest in symbol and ritual.

In concert with the technical and physical sciences (and the revolutionary biological sciences), the social sciences have played a prominent role in tying the university to social or national objectives, strengthening its place in the formulation of policies affecting the distribution of wealth, educational opportunities, the provision for social services, and other polemical issues that are the concern of modern, mass democratic societies. The entanglements with powerful and influential outside interests are not to everyone's liking, as they compromise the university's decision-making independence. However, the university has never been a wholly autonomous institution, not even within free and liberal societies. Such relative independence as it enjoys is the result of negotiation or 'social contracts' that each generation of university leaders, teachers, and researchers is destined to conduct.

Controls over Disciplinary Formation

The organization of the disciplines varies in different national and university settings, affecting the kinds of disciplinary emphases receiving attention.

The Chair-Holder System

The medieval faculties were the ultimate internal determinants of the curriculum, with alternative institutions such as colleges providing some opportunities for independent innovations. Centuries later, with the evolution of the professorial or 'chair' system of academic leadership, best known in its German form, individual chair holders administered 'institutes' and laboratories and set the standard for teaching and research, especially at advanced levels. Although the institute structure was embedded in the traditional faculty structure, changes had occurred that made chair holders and deans the effective authorities, and they respected one another's independence.

This system, which became standard in continental Europe, Latin America, Israel, Japan, and wherever else the German model of a university took hold before 1939, led the way in world scholarship and science. One essential drawback, however, was that younger academics with newer specialties could not easily find room within the old academic structure. They had two options: to await chair vacancies at home or elsewhere, or to persuade institutions (and the government ministers who largely controlled financing, especially after the later nineteenth century) to establish new or different chairs in developing subdisciplines. Before unification in 1870, 'Germany' was a collection of independent *Länder* competing against one another for professorial talent. Thus, intra-German rivalry itself was a variable in the formation of new fields of inquiry, along with the adoption of radical critical methods (the 'higher criticism'), and philosophical conceptions concerning personal development (*Bildung*) and research ('Humboldtianism').

The Disciplinary Department

Many of the features of the organization of knowledge that had evolved in Europe also existed in the United States, whose higher education system, first established in the colonial period, reflected English and Scottish influences, then French, and finally German ones. The chair-holder system was much in evidence throughout the United States as well, but by the end of the nineteenth century it was losing its authority as the arbiter of the curriculum. It was gradually supplanted by the 'department.' A century later, its main features had been adopted in most university systems elsewhere. A department is based on a discipline rather than a collection of disciplines (as in a faculty structure) and is run by committees. The department head, elected or appointed usually in rotation, is *primus inter pares*. Although senior and influential, chair holders and their equivalents share authority with other teaching titles. The

relatively 'democratic' decision-making apparatus of the department is broadly in keeping with medieval legacies of guild self-government.

Another US innovation, a credit-unit system of instruction that combines teaching and examining in a single person, was a departure from British and continental European external examining practices, and underscored the intellectual freedom of students and individual instructors and researchers. In this context, subdisciplines were able to flourish. While it is still possible for an entire department to be built or rebuilt along narrow and exclusionary disciplinary lines, such solutions are generally short lived given the independence of individual members and the variety of available funding sources.

One other US innovation of the twentieth century deserves mention: the advent of the graduate school. The continental European chair-holder system was suited to advanced instruction and the award of advanced degrees because it relied on a selective system of elite schooling – the *lycée* in France, the *Gymnasium* in Germany and Scandinavia, their counterparts elsewhere – and gave the professoriate discretion in choosing the best candidates for creative work. The US university, which for historical reasons was not well supported by an excellent system of secondary school instruction, recruited undergraduates of mixed preparation. The solution to the problem of how to offer research-level instruction was found in the establishment of a wholly separate administrative division freed from the necessity of providing remedial and general teaching. This innovation contributed greatly to the building up of strong research traditions within the social sciences and other disciplines. Versions of the American graduate school appeared in Europe during the 1980s and 1990s in response or reaction to governmental policies encouraging the development of mass forms of secondary and higher education. However, these have not been as significant as in America.

Before and during the introduction of departmental and credit-unit systems of instruction, the US pattern of disciplinary formation was similar to the European one. Subjects that did not find an immediate reception within traditional colleges and universities, especially subjects stigmatized as 'practical' (which could include modern languages), sought a more hospitable environment in alternative institutions. These had been springing up ever since the American Revolution.

By the end of the nineteenth century, liberal arts colleges, comprehensive universities (combining professional and liberal education), specialized institutes (such as the West Point Military Academy), prestigious polytechnics (such as the Massachusetts Institute of Technology), a German-style 'research university' (the Johns Hopkins University), and state institutions with not only applied but also liberal education missions (the 'land grant' universities) were members of a differentiated system that had expanded in connection with national ambitions, market conditions, and a federal constitution.

Within the older US colleges and universities, internal reconfiguring took place alongside external differentiation. In the earlier nineteenth century, academic subjects such as the natural sciences or modern languages that were not necessarily applied but were regarded as inimical to prevailing teaching values were able to create alternate degree tracks, if not of equivalent prestige. Within the senior English universities of Oxford and Cambridge, subject-based 'schools' (Oxford) or 'boards of studies' (Cambridge) representing specialties effectively replaced the medieval faculties structure. As in the German case, professorial chair holders controlled the university system of lecturing. However, as Oxford and Cambridge were collegiate universities or federations of relatively autonomous societies (legally 'charitable' societies), the professorial system did not constrain the whole system of instruction. The collegiate structure with its small classes and tutorial arrangements in fact liberated the professors from routine or introductory teaching.

Criticisms of the Departmental Organization

The flexibility inherent in a departmental organization and its comparative openness to innovation reduce the temptation for subjects to migrate toward alternative institutional structures. Departments are therefore one of the factors that have brought the 'university' institutional form into the center of modern society as the principal source of knowledge generation and dissemination. Factors other than departmental organization – and they are outside the scope of this article – may include national imperatives, such as war and industrial competition, mass higher education requiring extensive private but especially public resources, professionalism, consumer economies, and the high division of labor so typical of contemporary society.

Yet the departmental organization has its critics. Discipline-based departments as collections of specialists are said to be protective of privileges and unreceptive to cross-disciplinary fields of study. A similar criticism but with a different purpose arises from the defenders of the US tradition of liberal education. Departments are attacked as the chief obstacles to the development of general education studies for undergraduates. In both instances, the response has been the creation of interdisciplinary or multidisciplinary departments, or cooperative programs of teaching, as well as special appointments in broad fields such as 'Humanities' or 'Social Sciences.' Such experiments are now typical of newer European universities.

But an opposite kind of blame has also been voiced, most notably by two famous US *enfants terribles*: the maverick Thorstein Veblen at the turn of the twentieth century and the more establishment 1930s critic Abraham Flexner. Both excoriated US departments for being far too open to innovation, fads, and market demand, and far too eager to attract the financial support of philistine parvenus. Flexner in particular admired the German university tradition with its high intellectual standards and *Kultur*. For him, the elite characteristics of the European higher educational system – the alliance between government bureaucrats who decided educational budgets and chair holders who controlled institutes – meant that demands for the teaching of subjects unworthy of incorporation into the noble inheritance called a 'university' could be successfully resisted.

In the twentieth century, the views of critics like Flexner proved to be shortsighted. Totalitarian governments in Nazi Germany and the communist states of Central and Eastern Europe, as well as their copies elsewhere, provided vivid lessons of how knowledge could be manipulated from above and turned from its natural channels of curiosity and negotiation to unimaginable and terrifying applications. The university

systems of those countries had to be rebuilt after World War II, and the task remained unfinished as the twenty-first century commenced.

Universities of the Twenty-First Century

While it is nearly an axiom of twenty-first century, higher education policy in all democratic societies that universities must be flexible in providing access, instruction, and research, disagreement exists on the institutional forms best suited to promote those ends and whether traditional educational values will prevail.

The Entrepreneurial University

Technologies associated with the arrival of massive open online courses employing the Internet as well as the possible competition of degree-granting 'corporate' universities have issued new challenges to all existing forms of higher education. One response is to adopt the new technologies and emphases and assimilate them to the existing fabric of the university. This in fact is being done on a significant scale, although critics fear that in the process, the inherited character of the university will suffer if the emerging teaching technologies and different kinds of research priorities are not accommodated to accepted structures and norms. The new research environment is heavily weighted toward market discipline, government demands, and problem solving in national and global markets since these are the dominant sources of funding. Nevertheless, it is hoped that even entrepreneurial outreach will be infused with less commercially inclined values regarding objectivity and curiosity in knowledge generation. The battles continue.

Fading Institutional Boundaries

Modern society is dynamic; its economy is a whirligig. All institutions are affected: families, churches, schools, labor unions, government agencies, philanthropies, and industrial organizations. The boundaries between them are permeable and 'transgressive.' University identity and academic loyalties are therefore facing formidable challenges. These have already succeeded in altering the attachments of academics to universities. For some, the university is no more than a *pied-à-terre*, a temporary convenience while larger research ambitions are pursued in a variety of other institutional directions. One body of analysts has noted that research projects are often cooperative undertakings by teams composed of university and nonuniversity representatives and that many joint projects actually originate outside universities in government laboratories or industrial firms. Universities are therefore not the only sources of innovation. Much research is not even open ended as in the traditional university but commissioned, 'commanded,' or 'strategic' (one carryover from the global wars of the twentieth century).

Another consequence of looser institutional boundaries is the greater flow of individuals from one institution to another as philanthropies, government agencies, the military, private or nonprofit think tanks, industries, financial bodies, and even the media exchange players, providing new colleagues and settings for intellectual activity. Such institutions are therefore tied together in mutually reinforcing networks. Rival research sites have existed for centuries, whereas, as noted earlier in the formation of alternative institutions, the circulation of those with academic qualifications has never been greater than today.

The flows of educated talent is greatest in the medical, biological, physical, and technical sciences, but the policy sciences have also profited, as well as social disciplines oriented toward problem solving in circumstances where city planners, environmental experts, health workers, education specialists, psychologists, economists, criminologists, and social workers are required. The opportunities for movement are less certain in the humanities and 'soft' social sciences. The differences between knowledge domains are accordingly sharpened, leaving certain of the humanities and social sciences as weakened guardians of the university's traditional boundaries and self-understanding.

A Primary Role for Universities

Nevertheless, even as great changes affect the nature of the research university, and those connected to it, the fact remains that all institutions depend upon university-based disciplines (whether housed in departments or in new 'centers') to educate and train the talent required for the success of a modern, professionalized nation. The university remains the primary home of the academic profession, or, to quote a social historian, the academic profession is the 'key profession' because it educates all the others.

Social Science Infrastructure: North America (Research and Teaching)

Gisèle Yasmeen, Research – Social Sciences and Humanities Research Council of Canada, Ottawa, ON, Canada

This article is a revision of the previous edition by D.L. Featherman, volume 11, pp. 7503–7511, © 2001, Elsevier Ltd.

Abstract

This article discusses two types of infrastructure: the first, pertaining to general scholarly infrastructure for the purposes of networking and the exchange of knowledge (i.e., scholarly infrastructure, also known as 'institutions'), and the second regarding infrastructure for the conducting of research itself (i.e., research infrastructure). The article provides a historical overview of the development of both types of infrastructure in both the United States and Canada. Finally, current and future challenges, particularly with respect to cyberinfrastructure are dealt with in the conclusion.

The preservation and advancement of knowledge presupposes an infrastructure that sustains research and exchange of new information, prepares requisite personnel, and advances cumulative knowledge of the empirical world and theoretical insights. This is no less true in the social sciences than in the natural sciences. While scholarship is increasingly international, with its own sustaining infrastructure, a base for advancing and preserving knowledge exists within each country. In the United States, the foundations of the existing infrastructure for the social and behavioral sciences (hereafter, social sciences) were laid in the early decades of the twentieth century and expanded after World War II (WWII). In Canada, some foundations were laid both before and after WWII and were further developed and consolidated beginning in the late 1970s. Certain limitations of this infrastructure are now becoming apparent, particularly as the full potential of the digital age calls for increasingly sophisticated cyberinfrastructure for research, and scholarly enterprise more generally. If not urgently addressed, these factors may constrain the development of the US and Canadian social science and may hinder the realization of an international science of society as the twenty-first century unfolds.

What Is Infrastructure?

There are two types of infrastructure required for the social sciences to flourish. While the two are related on an empirical level, they are kept analytically distinct for this article. One type – 'scholarly infrastructure' – is the organizations and institutions, such as national academies and scholarly associations, funding sources and review systems, libraries, databases, theoretical models, methodologies, journals and other communication media, and advanced training programs that separately and collectively sustain and promulgate the research enterprise. In the digital age, this has expanded to include "emerging topics such as linking publications to research data, combining licensing with open access or enhancing repository networks through 'services on top of repositories' such as usage statistics, text/data mining, research profiles etc" (see Association of European Research Libraries Web site).

The second type of infrastructure is required to conduct research itself. For most of science, 'research infrastructure' conjures up images of national laboratories, orbiting telescopes, polar weather stations, or supercolliders; in other words, research instruments are maintained at great expense. What this image misses are less tangible research resources, such as databases and data mining tools that sustain and advance the research enterprise. This is especially true for the social sciences for which the 'brick and mortar' components of infrastructure are fewer and less obvious (CBASSE, 1998).

Research infrastructure is defined as 'single-sited' or 'distributed' resources, including facilities, equipment, instruments, and related services used to conduct research. This includes "knowledge-based resources such as collections, archives, or structured scientific information; enabling Information and Communication Technology based e-Infrastructures such as Grid, computing, software, and communication networks" (see OSIRIS Web site).

Research infrastructure emphasizes shared and sustaining resources that not only make scientific research possible, but also to add value to research activity. 'Shared' refers to what is accessible as a public good for science, something whose value is not diminished by multiple uses or that produces economies of scale or multiplier effects. For example, a multimillion-dollar investment in building an instrument for magnetic imaging of the mind is much like a similar investment in a 10-year panel study of a nation's youth as they leave school and enter the workforce. Many investigators can use both 'instruments' for a great variety of studies, each of whose value is not diminished, indeed, perhaps even made greater by virtue of others using the same instrument for different projects. This is especially true when such projects – all conducted at low additional marginal costs because of the same base investment in the 'instrument' – allow for the aggregation of information and therefore newly emergent information not available from separate studies. For example, multiple time series of different topical domains might cross-reference brain images over time in cognitive and in emotional activity, or, from the same sampled cohort, might interrelate the economic outcomes of the school to work transition and of the trajectories of social development over the same period. The term 'sustaining' refers to necessary resources without which the advance of knowledge would be slowed or halted, or, would be very expensive to nearly impossible to reconstruct if left to deteriorate. For example, with respect to scholarly infrastructure, if the funding of the National Science Foundation (NSF) were cut in half for

a 4-year period because of a change in priorities, research universities might be forced to close some institutes, and some might even redirect their missions. From a research infrastructure standpoint, a 40-year time series on the American or Canadian electorate, broken for a decade, may never retrieve the value it would have had were it not interrupted.

Historical Development of Scholarly Infrastructure

In both the United States and Canada, the foundations of the infrastructure of the social sciences were laid in the two decades prior to WWII and just after its conclusion (Fisher, 1991; Prewitt, 1995; Bulmer, 2001).

The United States

Prior to WWII, a remarkable convergence of interests within the leadership of private philanthropy and of the burgeoning social science disciplines and their national associations yielded an extraordinary array of institutions and resources that were to both consolidate and accelerate the growth of social research.

Private philanthropy by industrial capitalists like Andrew Carnegie, the Rockefellers, and Russell Sage in the nineteenth century provided the initial means for social science's development in the early decades of the twentieth century (Bulmer and Bulmer, 1981; Prewitt, 1995). These private foundations created the first explicit scholarly infrastructure for social science. Whether this investment was motivated by the self-protective interests of a capitalist social class (i.e., Fisher, 1993) or reflected deeper religious and humanitarian concerns in the public interest (i.e., Bulmer, 2001; Lagemann, 1989) can be debated. In any case, the early infrastructure of social science emerged from a fortuitous convergence of the announced goals of philanthropic foundations and the coalescence, within the USA, of defined social science disciplines – history, political science, psychology, economics, anthropology, and sociology (Ross, 1991). An important additional element of that early infrastructure was the creation of graduate schools at a few universities, starting at Johns Hopkins in 1876 and then at Clark, the University of Chicago, Columbia, Harvard, and Yale.

As for the foundations, leaders such as psychologist Beardsley Ruml at the Laura Spelman Rockefeller Memorial drew inspiration from the natural and medical sciences as a means of understanding and, it was presumed, controlling the empirical world and set as a goal the creation of a corresponding science of society. This science was not an end in itself; it did not reflect so much a commitment to knowledge per se than to use rational analysis and scientific research to reveal the 'root causes' of the massive problems of industrial America and thereby to overcome them. Investment into research and the scientific enterprise, e.g., into the putative causes of urban poverty rather than exclusively into assisting poor families, reflected a broad sea change in the goals of private philanthropy in the early decades of the twentieth century (Prewitt, 1995). This change in philanthropy led to the creation of several research institutes in medicine and the natural sciences, e.g., the Rockefeller Institute for Medical Research in 1901. But it also coincided with the rapid emergence of several additional foundations and organizations that supported the development of social and behavioral research (see Table 1).

The early history of the Social Science Research Council (SSRC) amply illustrates the evolving close partnership between private philanthropy and university-based research of the social science disciplines after World War I (WWI). At the core of this history is a very effective network of leadership within the foundations and the small set of elite university research programs – leadership that circulated between these two worlds and galvanized common cause to promote a science of society. Charles F. Merriam, president of the American Political Science Association, spearheaded a cadre of counterpart economists, sociologists, and historians (and joined later by anthropologists and statisticians) with commitments to a scientific approach in their respective fields but also to multidisciplinary research inquiries. They founded the Social Research Council (SRC) in 1923 to use a scientific, interdisciplinary approach in analyzing the problems of society, to develop new methodological tools for this purpose, and to assist university-based academic programs in training a new generation of social scientists for this agenda. Merriam and colleagues considered but ultimately rejected the idea of affiliating with the American Council of Learned Societies – one of the first councils to span the social sciences and humanities. Instead, they pursued, unsuccessfully, incorporation within the National Research Council (NRC), the operational arm of the National Academy of Sciences, which at that time incorporated only the fields of psychology and anthropology, the disciplines bearing closest affinity with the natural sciences. The SRC might have failed were it not for Beardsley Ruml, newly appointed director of the Laura Spelman Rockefeller Memorial and recent PhD in psychology from the University of Chicago. By 1922, Ruml had $2 million per year to invest in developing a science of society, but he was uncertain that university-based disciplinary departments, or the associations per se, would progress rapidly in that direction. Ruml had endorsed Merriam's unsuccessful bid to be incorporated into the NRC and suggested that the SRC add 'Science' to its name, and thus, it became the SSRC. Subsequently, Ruml and the Memorial began a steady flow of financial resources to the SSRC, and through it to university-based faculties to develop their methodological capacities and the volume of science-inspired research into the burgeoning set of social problems of the era. During this era, the SSRC functioned as the social science counterpart to the NRC and at the same time served as adjunct to the Memorial as a 'pass-through' foundation. Between 1923 and 1929, the Memorial distributed about $40 million for social research and advanced (quantitative) methodological training, much of it distributed through the SSRC (Bulmer and Bulmer, 1981; Featherman, 1994).

As for the social science disciplines themselves, their progress as research fields can hardly be understood without acknowledging the catalytic importance of universities. This includes their gradual transformation as centers for academic research as well as for their original mission of educating undergraduates (Geiger, 1993). Here, too, the role of foundations and private investment in creating this element of infrastructure in the early twentieth century cannot be overlooked, even though their support of universities was quite selective and targeted (Bulmer, 2001). For example, the Rockefellers

Table 1 Milestones in the USA and Canada in the creation of scholarly infrastructure

USA	*Canada*
1865: Creation of the American Social Science Association (precursor to the American Economic Association and the National Conference of Charities and Corrections;	1882: Establishment of the Royal Society of Canada (RSC) by an Act of Parliament as the senior Canadian collegium of distinguished scholars, artists, and scientists. The RSC represents all fields of knowledge.
1876: Creation of graduate programs in the social sciences beginning at Johns Hopkins University, followed by Clark, University of Chicago, Columbia, Harvard, and Yale	
1903–27: Emergence of foundations and organizations supporting social and behavioral research – General Education Board (1903); Milbank Memorial Fund (1905); Russell Sage Foundation (1907); Carnegie Corporation of New York (1911); National Bureau of Economic Research (1921); Social Research Council (1923); Brookings Institution (1927); Social Science Research Council (1923)	Establishment of the National Research Council in 1916 (for the natural sciences and engineering). Establishment of ACFAS in 1923. The acronym originally stood for *Association canadienne-française pour l'avancement des sciences* and was renamed *Association francophone pour le savoir* with the original acronym conserved in 2001. The organization represents all fields of knowledge.
1929: President Herbert Hoover's appointment of a Blue Ribbon Panel to assess trends in American society, especially in the aftermath of the stock market crash.	1940: Creation of the Canadian Research Council in the Social Sciences Creation of the Royal Commission on National Development in the Arts, Letters, and Sciences (i.e., the 'Massey Commission') was officially appointed on 8 April 1949 by Prime Minister Louis St-Laurent and completed its work in 1951 1943: Creation of the Humanities Research Council of Canada (subsequently the Humanities Federation of Canada) 1951: The commission recommended significant investment in art, science, and culture and led to the creation of the National Library of Canada (now Library and Archives Canada) and the Canada Council for the Arts established in 1957.
1950: Creation of the National Science Foundation	1978: Creation of the Social Sciences and Humanities Research Council of Canada
1973: Creation of the National Institute of Education	
1990s: Full directorate status for the social and behavioral sciences at the National Science Foundation	1996: Merger of the Social Science Federation of Canada and the Canadian Humanities Federation
1995: National Institutes of Health (NIH), Office of Behavioral Research was opened with a direct reporting line to the Director	2000: Creation of the Canadian Institutes for Health Research, modeled on the NIH and replacing the Medical Research Council of Canada and expanding its mandate to include funding of all aspects of health research, including by social scientists. 2005: Creation of the Council of Canadian Academies

provided foundational financing for the University of Chicago and encouraged its evolution toward a research and teaching university. While the modern research university was not to emerge in the USA until after WWII, universities like Chicago and Columbia were notable incubators of empirical social scientific inquiry much earlier than 1940. At Columbia, for example, statistical research began in 1890 under the influence of Richmond Mayo-Smith and Franklin Giddings who were focused on local conditions and problems of urban life. Later, just prior to WWII, the Bureau of Applied Social Research under the leadership of Paul Lazarsfeld elevated Columbia's prominence in empirical social science and embraced national issues. This broader scope was a context for refining social theories and quantitative methodologies.

Elements of this new infrastructure included the University of Chicago and its celebrated Chicago School of Social Research, the SSRC in New York City, the National Bureau of Economic Research, and what later was to become the Brookings Institution. In the later period, with the rapid evolution of the federal administrative state following the great depression and WWII, the NSF and the National Institutes of Health (NIH) funded an expansionary phase of research. Most of this science-building activity occurred within the nation's research universities, themselves a product of the postwar era. The course of social sciences in the USA reflects the history of its infrastructure just as much as it does the intellectual biographies of its leaders and evolving corpus of scientific contributions (Deutsch et al., 1971).

The effectiveness of university–government partnership during the war prompted President Truman and Congress to establish the NSF in 1950. The size of the role for federal support of civilian research and development (R&D), especially for the support of 'basic' research during peacetime, was debated. And the place of the social sciences – viewed at best as 'applied' and not a 'basic' science – within the mission of the NSF, was heavily contested. Expenditures for these fields represented a mere 1.2% of the NSF budget in 1956 and only grew to 1.6% ($890,000) by the end of NSF's first decade (Larsen, 1992). Additional support for social and behavioral research emerged in an expanding NIH in the postwar years, although the NIH focused its resources on biomedical and other health-related science. Indeed the pattern of scattering federal support for science across agencies has sometimes impeded a consolidated and centralized federal science policy (and corresponding decentralized decisions about science funding) since the close of WWII. Funding for the social sciences came less from federal sources than from the foundations, but on a steadily declining basis after mid-twentieth century.

During the same postwar period, economists – most prominently among social scientists – were recruited into new elements of an expanding Executive Branch. The President's Council of Economic Advisors was established in 1946. But the most rapid expansion of the federal administrative state occurred in the 1960s during the Kennedy and Johnson presidential administrations; the federal government became one of the largest employers of social and behavioral scientists (Featherman and Vinovskis, 2001). This was a period of jarring racial turmoil and wide public perception of unsolved and long-standing social problems of crisis proportion, such as poverty amid plenty. The Great Society initiatives of the Johnson presidency, and large federal social welfare expenditures (over $60 billion in 1970, a 142% increase over the decade), drew upon social science research for technical guidance. At the NSF, a Social Science Division was created, somewhat expanding the legitimacy of these fields. Similarly, Congress created a National Institute of Education in 1973 to promote a broad agenda of research and evaluation of school reforms. Correspondingly, support for social research blossomed from $384 million in 1961–62 to $803 million in 1966–68, half coming from federal agencies (Featherman and Vinovskis, 2001). During this period, both academic and more policy-oriented social scientists joined faculties of programs and schools of public policy at a growing number of research universities. Thus, as during WWII, the so-called War on Poverty and associated aspects of the Great Society added to an expanding infrastructure, its funding, and its personnel base for social and behavioral sciences.

If the 1960s and early 1970s constituted something of a 'golden era' for social science, its infrastructure, and the role of its practitioners in policy circles, the era did not last long and ended for many in disillusionment. Large-scale quasi-experiments such as Project Head Start and the Negative Income Tax experiment, conceived and designed by social scientists in league with public policy officials, failed to demonstrate large or lasting impacts (White and Phillips, 2001; Gueron, 2001).

Solutions to social problems proved far fewer, more intractable, than promises; and social scientists argued openly among themselves about seemingly arcane (to politicians and the public) reasons for failure (Aaron, 1978). Politicians and the public gradually came to the view that public monies invested in social research were irrelevant if not wasteful. Meanwhile, another war, this one in Southeast Asia, deeply divided the American public during the Johnson and Nixon presidencies. Academics in general, and social scientists in particular, tended to oppose this war. From the perspective of the more politically conservative administrations of Presidents Nixon and Reagan, the Vietnam War had so politicized and radicalized the professoriate that scholars, especially in the social sciences, were no longer seen as providing impartial research and evaluations (Featherman and Vinovskis, 2001). By the mid-1980s, federal funding for the social sciences had been cut back draconically.

In the closing two decades of the twentieth century, a few events affected scholarly infrastructure of the social sciences. Following the Watergate episode and resignation of President Nixon, Americans grew more cynical of Washington, and government itself. Academic social scientists, perhaps with the exception of economists and lawyers, retreated to universities to undertake more theoretically inspired research. Those with a policy orientation either joined expanding faculties in schools of public policy or were recruited into a rapidly proliferating set of partisan think tanks (both liberal and conservative) that ringed the Capitol to provide politically inspired analysis and commentary to their respective constituencies.

Canada

In Canada, fledgling activities in the social sciences – as well as the humanities – went through similar soul-searching with respect to the relationship with government, the relationship between what were seen as 'purely' scholarly or scientific pursuits and those with a more 'applied' or 'problem-based' orientation. Canadian activities in the social sciences were initially supported by American foundations such as Carnegie and Rockefeller or specific activities such as conferences and publications (Fisher, 1991). This was, in many ways thanks to the prominence of and respect afforded to individuals such as Harold Innis who played instrumental roles in the development of social sciences both in Canada and on the world stage. The University of Toronto, McGill, and Queens were the three universities where social science research was the most developed at the time in English-speaking Canada. The SSRC of Canada – established in 1940 – eventually transitioned to become the Social Science Federation of Canada. Together with its sister organization, the Canadian Federation of the Humanities, the Council successfully advocated along with other scientific, cultural, and artistic interests for the establishment of the Royal Commission on National Development in the Arts, Letters, and Sciences (i.e., the 'Massey Commission') spurred by fears of the influence of the United States, the Commission was a large-scale consultative enquiry into the state of Canadian scientific and cultural institutions, the Commission led, ultimately to the creation of the Canada Council for the Arts and subsequently, the Social Sciences and Humanities Research Council. The Humanities and Social Science federations merged in 1996 for practical reasons but perhaps also, it might be argued, due to more blurred conceptualization of the social sciences and humanities in Canada where scientific and interpretive methods coexist. This may be due to the francophone presence in Canada and greater European influence where 'science' is often viewed more broadly as codified knowledge, as opposed to associated solely with the scientific method. Indeed, the francophone presence has had a significant impact on all aspects of scholarship in Canada including conditioning the formation of scholarly infrastructure (Gingras, 2006).

The Foundational Period of Research Infrastructure: Before WWII

While scholarly and research infrastructure are deeply intertwined, this section delves into the foundations of research infrastructure itself in both the USA and Canada, with a focus on the development of shared and sometimes capital intensive resources and tools, which have made the social research enterprise possible (**Table 2**).

Table 2 Examples of significant social science research infrastructure

The United States	*Canada*
The United States Census: Undertaken since 1790, it gradually developed into viable research infrastructure beginning in the nineteenth century.	Canadian Census: First conducted in New France in 1666 and, in British North America, beginning in 1871 2001 – The first Research Data Centers established 2006 – Compute Canada funded 2010 – Canadian Polar Data Network
Hull House Maps and Papers: Du Bois 'The Philadelphia Negro'; the Pittsburgh Survey	Ethnographies of indigenous peoples in Canada by anthropologists and missionaries
National Elections Studies	1965 to Present – Canadian Elections Study 2001–09 to present – Canadian Longitudinal Study on Aging
International: Luxembourg Income Study (comparative database)	

The United States

At the close of the nineteenth century, the roots of American social science drew their energy from investigative journalists, reformers in settlement houses, and statisticians seeking to count unemployment and develop reliable representations of labor markets in local areas (Bulmer, 2001). Statisticians such as Carroll Wright developed crude labor statistics for the state of Massachusetts after the civil war, mirroring the 'statistical movement' in Victorian Britain and the 'probabilistic revolution' pioneered by Quetelet and others in Europe during the early to mid-nineteenth century (Bulmer et al., 1991). What drove even this descriptive, social statistical enterprise was related to reformers and advocates for the poor like Jane Addams and W. E. B. Du Bois at the beginning of the twentieth century. Hence, social sciences at the time were fueled by a progressive social reform ideology, and extended to concerns about the fragility of democracy and threats to economic self-sufficiency in an America beset with racial and labor conflicts, massive numbers of immigrants, and unstable economic cycles with impoverishment for many.

Devoted to improving the lot of urban poor, the Settlement House movement, inspired and drew upon a series of mapping projects and urban surveys, e.g., Hull House Maps and Papers; Du Bois' The Philadelphia Negro, the Pittsburgh Survey. These protoscientific inquiries of the late nineteenth and early twentieth centuries, some commissioned and funded by the Russell Sage Foundation in the interests of improving social welfare, comprised one element of the Social Survey Movement. They, in turn, gave impetus to what was to become modern statistical sampling and survey research during and just after WWII (Converse, 1987; Bulmer et al., 1991).

Likewise, at the University of Chicago, the seminal empirical studies of W. I. Thomas on Polish immigrants to Chicago (published in five volumes with Florian W. Znaniecki from 1918 to 1920) gave rise to a 'Chicago School' of sociological research in 1915–35 under Robert E Park, Ernest Burgess, and William F Ogburn (Bulmer, 1984). It also led to a nascent science of American politics after 1920, with leadership from Charles Merriam and his students Harold Gosnell and Harold Lasswell.

Throughout the foundational period, however, the government of the USA played a rather insignificant role in creating the early infrastructure of the social sciences. Most government existed at state and local levels; the federal administrative state grew in size and importance after the great depression and WWII. While the USA Census dates from 1790, the US Bureau of the Census was created as a permanent federal agency in 1902. Other elements of a federal statistical system emerged subsequently.

Events such as wars and economic depressions, and governmental response to them, guided the evolution of the social sciences during the foundational period. For example, during WWI the mobilization of American men, (and their screening for fitness, and assignment) gave rise to nonexperimental, but nonetheless quantitative psychology, to the psychometric assessment of personality and mental abilities (drawing upon European precursors). This war effort spawned 'basic' research on individual differences, as well as an industry of psychological and educational testing (Carson, 2001).

William Ogburn, a Chicago sociologist, headed the SSRC research effort and filed its multivolume report, *Recent Social Trends in the United States*, in 1933 after President Hoover left office. The report took the view commonly accepted at the time: if facts and trends about households, towns, and institutions could be clearly discerned and precisely measured, then surely rational decision makers would use the information in the public interest. This view contrasted sharply with the orientation of the Social Survey Movement earlier in the century, when data were collected directly in the service of correcting urban problems (Bulmer, 2001). However, the report was widely criticized. Within elite academic circles, such as the leadership of the SSRC, reservations emerged about the potential distorting effects of association with political agenda setting, especially the compromise of scientific impartiality as a basis of intellectual inquiry. In the emerging federal policy world of the New Deal era, the report was dismissed for its lack of politically informed analysis and interpretative prescription: the facts could not and would not speak for themselves. What administrative decision makers of the emerging federal state sought was knowledge for action in a political arena and tested against the requirements of political decision making rather than against the requirements of academic social science professionals seeking legitimacy through impartiality (Lynn, 2001).

Canada

With respect to research infrastructure in Canada prior to WWII, it is important to keep in mind that – despite confederation and political independence from Britain in 1867 – a colonial mindset and structure in the world of academe prevailed. Hence, European and American influences were strong and the uniqueness of Canadian perspectives and research resources were not yet fully appreciated. Yet, there were periods of seminal transformation, which might be

considered the equivalents of some of the pathbreaking work seen in the USA in the same era. For example, Franz Boas, the father of modern anthropology, studied the indigenous peoples of the Pacific Northwest in British Columbia the Canadian High Arctic. In the nineteenth century, early Christian missionaries, particularly Roman Catholics such as Father Adrian-Gabriel Morice, but also Moravians and Methodists, documented languages, customs, and family structure, which later served as legal evidence in modern land claims.

Subsequently, the dominant Euro-Canadian society set out to complement the economically oriented theories developed by the likes of Harold Innis, W.A. MacIntosh, D.G. Creighton, and J.M.S. Careless. The publication of sociologist S.D. Clark's *The Social History of Canada* in 1942 might be seen as an important milestone in the development of a repertoire of knowledge at the time featuring a comprehensive approach (see The Canadian Encyclopedia Web site). Similar attention by both French- and English-speaking social scientists to the francophone presence is a distinguishing feature of the growth in research infrastructure at that time. H.B. Ames' pioneering sociological study of working-class Montréal, *The City Below the Hill* (1897; reproduced in 1972) is one example. Canadian social and economic analyses were influenced by both the Annales School as well as British social history. Geography also played a key role in the development of research resources such as mapping. Donald Fisher's The Social Sciences in Canada: 50 Years of National activity by the Social Science Federation of Canada (1991) provides copious detail on other similar tomes, which laid the foundations of Canadian social sciences prior to WWII.

Period of Punctuated Evolution: After WWII to the Early Twenty-First Century

In both the United States and Canada, the period after WWII represented a flourishing of research infrastructure, in part, due to the economic growth that distinguished the postwar era and the associated growth in universities and postsecondary training. This section points to a few key developments.

The United States

The great depression, New Deal, and subsequent American participation in WWII contributed to growth in the size and political scope of the federal administrative state. Scientists and engineers, as well as their social and behavioral counterparts, contributed to the war effort in a wide variety of federal agencies. Within the Department of Agriculture, for example, studies of the war's impact on the farm economy and households gave rise to more refined survey research and its technology, especially probability sampling. Because science and technology were so instrumental to the war effort, federal expenditures on R&D rose from $100 million in 1940 to $1.5 billion in 1945 (Featherman and Vinovskis, 2001). Thus, WWII created the funding infrastructure for a lasting partnership between the federal government and universities and stimulated the flourishing of the research university.

The abundant infrastructure of the golden era, especially in the form of repeated cross-sectional surveys (e.g., the Current Population Surveys; the National Election Studies), longitudinal studies (e.g., Panel Study of Income Dynamics; National Longitudinal Surveys of Youth), and quasi-experiments or intervention studies (i.e., Gueron, 2001) provided common databases for both academic- and policy-inspired research and for often fierce partisan debates over issues such as welfare reform (e.g., Danziger, 2001). Many of these surveys owe their existence to the Bureau of Applied Social Research at Columbia as well as the growth of the rival 'Michigan School' (Johnston, 2011).

Canada

In Canada, the aftermath of the Massey Commission and its legacy of public funding and institutions allowed for the development of systematic research infrastructure resources to nurture research in the social sciences. Examples include, the Canadian Election Study (CES), which is "among the world's oldest academically-based national election studies, with an almost unbroken record of fieldwork dating back to 1965" (Johnston and Blais, 2008) and Canadian contributions to comparative international data sets such as the Luxembourg Income Study. The CES may have unwittingly been a 'nation-building' exercise, as it was one of the first longitudinal data sets to involve cooperation by both English- and French-speaking social scientists. Indeed, in the development of survey research owe a debt to Canadian social scientists through advances in the use of repeated cross-sections (Johnston, 2011; Brady and Johnston, in press) and earlier pioneering work done by Canadian Saul Forbes Rae in collaboration with George Gallup (Gallup and Rae, 1940).

In the 1990s, Canada witnessed a significant turning point in the development of more capital-intensive research infrastructure, in part due to the establishment of the Canada Foundation for Innovation and its mission to support capital investment in research infrastructure, often in collaboration with federal funding agencies. A prime example is the establishment of the Research Data Centers in 1998, which make social statistics available in secure facilities across the country in a manner that does not contravene the Statistics Act.

The turn of the twenty-first century witnessed other exciting investments into Canadian social science research infrastructure. A prominent example is the multi-institutional Canadian Century Research Infrastructure initiative (2003) designed to digitize census data and make it accessible and interoperable. Another key development was the establishment of the Canadian Longitudinal Study on Aging (CLSA), "a large, national, long-term study that will follow approximately 50 000 men and women between the ages of 45 and 85 for at least 20 years." The development of the CLSA from 2001 to 2009 was facilitated by the creation of the Canadian Institutes of Health Research in 2000, modeled on the US NIH, and mandated to fund all aspects of health research, including from social science perspectives. In addition to collecting new data, the CLSA, also cleans and makes interoperable multitudes of existing data sets. Last, but certainly not least, the Canadian Polar Data Network is an outgrowth of the very successful data management undertaken supporting the context of the International Polar Year supported by the three national research granting agencies.

The Promise and Challenge of Big Data and Cyberinfrastructure

Now well into the second decade of the twenty-first century, the challenge and promise of cyberinfrastructure looms large. For decades, the European Science Foundation has led the way in developing successive science protocols, which take explicit account and fund cross-national projects and infrastructure elements such as data archives and advanced computational facilities on a shared, international basis (European Commission, 2010).

Nevertheless, forward strides have been taken in the past 10 years with respect to 'big data' and cyberinfrastructure in the USA and Canada. Cyberinfrastructure is defined as:

> the coordinated aggregate of software, hardware and other technologies, as well as human expertise required to support current and future discoveries in science and engineering. The challenge of cyberinfrastructure is to integrate relevant and often disparate resources to provide a useful, usable, and enabling framework for research and discovery characterized by broad access and "end-to-end" coordination.
>
> Berman, 2005

Cyberinfrastructure consists of computing systems, data storage systems, advanced instruments and repositories, visualization environments, and people linked together by software and high-performance networks to improve research productivity and enable breakthroughs not otherwise possible (see Indiana University UITS Web site). The USA and Canada have made considerable advancements in cyberinfrastructure in recent years.

In the USA, following a series of workshops in the early part of this century (see NSF Cyberinfrastructure Web site), the NSF created an Office of Cyberinfrastructure in July 2005 as a horizontal programing unit reporting directly to the Director of NSF. This resulted in creative funding for cyberscholarship across the US as well as the introduction of mandatory data management plans. By October 2012, the Office had been realigned as a unit within the Directorate for Computer and Information Science and Engineering (see University of Michigan Advanced Research Computing Web site).

In Canada, Genome Canada – which primarily funds 'laboratory' research but does provide support to social scientists working on the legal, economic, environmental, and social aspects of genomics – was a pioneer in data management and stewardship. Furthermore, the second edition of the Tri-Agency Policy Statement on Research Ethics provides best practices for the management of data. Canadian scholars have relished the opportunity to work creatively with their US and European counterparts for several editions of the Digging into Data challenge, which has also been a groundbreaking initiative in the field of big data and cyberinfrastructure.

In conclusion, both the USA and Canada have progressed substantially with respect to harnessing the potential of research infrastructure in the twenty-first century. By working together as well as with European, Asian, and collaborators from around the world, scholars in the social sciences – often in collaboration with the humanities or other fields of knowledge – are poised to make even more significant contributions to the preservation and advancement of knowledge.

Abstract

The institutional foundations for social sciences in Sub-Saharan Africa (SSA) experienced substantial transformations since the end of the colonial era. The region has seen a great mushrooming of new government-funded education and research institutions and currently has more than 700 universities, with the amount of private centers, institutes, networks, and nongovernmental organizations also expanding at a fast pace. Despite a significant increase in education and research infrastructure over the past half a century, the region also experiences an increasing backlog in capacity to accommodate an even faster increasing amount of social science students and scholars. The main challenge across the region is the lack of sufficient funding, particularly state resources, to keep pace with burgeoning populations and concomitant increases in demand for academic and research resources.

The purpose of this article is to provide an overview of the current state of the social sciences infrastructure in SSA, with specific reference to its funding, education, and research structures. One of the main findings is that the rapid growth in the number of students is proving to be a challenge to the sustainable financing of higher education. Africa is the only region in the world that has experienced a decrease in the volume of current public expenditure per student over the past two decades. This state of affairs is having an adverse impact on the quality, efficiency, and sustainability of education and research programs. As a result, and given that the state is the main source of funding for higher education in SSA, different forms of cost sharing to cover tuition and other types of fees (e.g., from household financing or student loan schemes) are increasingly being implemented in most African countries. Social sciences research in the region is predominantly practiced within the universities, but a few countries have research institutes or centers devoted to the social sciences. However, the most progress in terms of the development of social science structures appear to be at a pan-African level with networks such as Council for the Development of Social Science Research in Africa and Organization for Social Science Research in Eastern and Southern Africa making great progress in overcoming the challenges of fragmentation of social sciences activities and output in the region.

More specifically, this article also focuses on three case study countries in terms of different aspects of the social sciences; these countries are South Africa, the Democratic Republic of Congo, and Ethiopia.

Overview

Since the end of the colonial era, the institutional foundations for social science research, teaching, and related activities in Sub-Saharan Africa (SSA) have undergone significant transformation. Growing from a very small number half a century ago, there are now more than 700 universities in the SSA region (Ranking Web, 2014) and they are still increasing in number at a fast pace. New higher education institutions are being set up by both governments and private providers, while research centers, institutes, networks, and nongovernmental organizations (NGOs) are also burgeoning (Sall, 2010).

While many colleges and/or fully developed universities existed before independence across the continent, the development of social research and education of the social sciences is very much a postcolonial phenomenon (Mouton, 2010). However, the key concepts and theoretical frameworks with which most African scholars worked in the first independent decades were 'made in the West.' Subsequently, one of the main efforts of regional social science councils such as Council for the Development of Social Science Research in Africa (CODESRIA) and Organization for Social Science Research in Eastern and Southern Africa (OSSREA), and other professional associations of social science practitioners, has been to address challenges of autonomy by working toward building a networked, self-aware community of scholars. Some have been determined in creating a so-called 'African library' in order to replace what Mudimbe called the 'colonial library' (Sall, 2010).

However, one of the main challenges constraining growth in African-based social sciences research and education is funding. According to Tefera (2013), problems surrounding the financing of higher education institutions are worldwide; however, nowhere in the world is financing higher education more problematic than in SSA. The two main reasons for this challenge are the high and increasing unit (per student) cost of higher education; and the pressure for increasing enrollments due to rapid population growth including the fast increasing number of youth finishing secondary school with aspirations for tertiary education. There is a staggering need in Africa to raise enrollment numbers, which places severe pressure on regional governments. In many countries where a decade ago tens of thousands of students attended higher education institutions, the figure now amounts to hundreds of thousands. Given the strong link between higher education and development, it is now more crucial than ever for adequate resources to be invested into the sector in a sustainable and meaningful manner (Tefera, 2013).

Against the above, the purpose of this article is to provide an overview of the current state of the social sciences infrastructure

in SSA, with specific reference to its funding, education, and research structures. Three case studies – South Africa, the Democratic Republic of Congo (DRC), and Ethiopia – will also be put to the fore.

Social Sciences Infrastructure in SSA

Funding

The same as many countries in the world, the state is the main source of funding for higher education in SSA. However, the degree of dependence on the state is believed to be higher in SSA countries than internationally. Despite a lack of detailed data, it is reported that up to 90–95% of the total higher education operating budgets in the region is met out of government grants, with the remainder coming from student fees (Teferra and Altbach as cited in Tilak, 2011).

The rapid growth in the number of students is certainly a challenge to the sustainable financing of higher education. Africa has maintained its public investment in higher education between 1991 and 2006, allocating approximately 0.78% of its gross domestic product (GDP) and around 20% of its current public expenditure on education to higher education. However, during the same period, the total number of students pursuing higher education tripled, climbing from 2.7 million to 9.3 million at an annual average rate of 16%, while public resources allocated to current expenditure in that sector only doubled (an annual average rate of 6%). The decline in public expenditure per student is having an adverse impact on the quality and relevance of education programs. Africa is the only region in the world that has experienced a decrease in the volume of current public expenditure per student (30% over the last 15 years) (World Bank, 2010).

As a percentage of GDP, higher education has received a very small share in Africa, as the figures in **Table 1** suggest – far below 1%: namely 0.5% in Francophone Africa and 0.8% in Anglophone Africa (Tilak, 2011).

Apart from state funding, higher education in Africa also receives funding from the following sources (World Bank, 2010):

- *Private resources in higher education funding*: Faced with inadequate public financing, the share of private resources in higher education financing is expanding. The contribution from households accounts for approximately 25% of national expenditure (state and households) on higher education. It varies widely according to country, ranging from less than 10% in Mali, Chad, and the Republic of Congo to more than 50% in Uganda and Guinea-Bissau. However, household financing of higher education is relatively low when compared to household investment in other levels of education (30% of national expenditure in primary education and more than 45% in lower secondary education).
- *Cost sharing*: Different forms of cost sharing are being implemented in most African countries. As of 2009, at least 26 countries in Africa charge either tuition fees or other types of fees such as examination fees, registration fees, identity card fees, library fees, and management information system fees. Overall, higher education institutions in Africa generate about 30% of their income (from less than 5% in Madagascar and Zimbabwe to 56% in Uganda and 75% in Guinea-Bissau).
- *Financial aid programs*: To combine financial efficiency and equity goals, the introduction of tuition fees is accompanied by the development of financial aid programs and student loans. Financial assistance policies are critical components of cost-sharing policies in Africa. Most Francophone countries have privileged nearly universal financial assistance through free or subsidized social services (food, transportation, and housing) and scholarships for living expenses. Some have improved the targeting of public assistance and adopted means-tested policies. Student loans are operating in at least 13 African countries, mainly in Anglophone ones. Cost recovery remains the main challenge in most countries for student loans to be effective and sustainable.
- *External assistance to higher education*: International aid in support of higher education is on average US$600 million annually, or one-quarter of all international aid to the education sector in SSA. This relatively low share reflects the current emphasis given by most donors on the development of basic education and the achievement of Education for All. In addition to the small amounts of aid, two main factors limit the impact of aid. First, only 26% of aid to higher education goes directly to African universities and research centers. The remainder is provided through scholarships abroad or is accounted for by directly imputing student costs in the donors' universities. Second, aid is highly fragmented, owing partly to the lack of donor coordination. This imbalance in aid to higher education certainly limits its impact and makes its current allocation questionable.
- *Foundation support*: In addition to bilateral donors, foundations have played a growing role in financing higher education in Africa. Since 2000, seven American foundations (namely, the Ford, Carnegie, Rockefeller, MacArthur, Hewlett, Mellon, and Kresge foundations) plus the Partnership for Higher Education in Africa have made significant investments in African universities. Between 2000 and 2008, the partnership foundations contributed an aggregate of US$354 million toward higher education initiatives in seven countries (Ghana, Kenya, Mozambique, Nigeria,

Table 1 Public expenditure on education in Africa

	% of total government expenditure		*% of GDP*		
	Early 1990s	*Around 2003*	*Early 1990s*	*Around 2003*	*Higher education % of GDP, 2003*
Francophone Africa	22.9	17.6	3.3	2.7	0.53
Anglophone Africa	16.1	21.4	3.0	4.5	0.83
Other African countries	12.9	11.7	2.4	2.0	
Total Africa	19.3	18.2	3.1	3.3	0.63

South Africa, Tanzania, and Uganda) and on an Africa-wide basis. The most significant focus of the partnership has been the development of universities' physical infrastructure and human and organizational capacity. Information technologies and connectivity to the internet are at the core of these efforts, with investments until 2010 of more than US$30 million (World Bank, 2010). Most European and Scandinavian countries also have donor programs and projects directed at SSA, e.g., Sweden (Swedish International Development Cooperation Agency (SIDA)) and the United Kingdom (Department for International Development (DFID)).

Education

Colleges, university colleges, and/or fully developed universities existed before independence in countries such as Sierra Leone, Ghana, Nigeria, Ethiopia, Uganda, Senegal, Rhodesia and Nyasaland, Egypt, Morocco, Algeria, Tunisia, and South Africa. However, the development of social research and of the teaching of the social sciences is very much a postcolonial phenomenon. In many African states, the postcolonial state built most of the research and training institutions (universities, institutes, and centers) during the first few decades after independence (Mouton, 2010). As mentioned earlier, there are now more than 700 universities in SSA. However, the development of educational institutions is not currently keeping pace with the rapidly expanding demand.

Ebrima Sall (cited in Mouton, 2010) identifies five factors that are particularly important in understanding the context of social science teaching and research in Africa:

1. economic change (from developmentalism to decline and liberalization);
2. social change (changes in the status of large sections of the elite from high to low, rapid urbanization, and a rise in mass poverty);
3. political change (authoritarianism, followed by liberal democratic reforms in some countries, conflicts and civil wars in others);
4. change in information and communication technologies; and
5. change at the level of the university and other social research institutions (expansion of the sector and diversification of types of institutions and governance systems).

Given these factors (among others), the SSA region finds it increasingly more difficult to ensure the supply of sufficient educational infrastructure. A common result of this inadequacy is high levels of 'out-migration' of social science students. In addition to the well-known flight of high-level human capital (academics and scholars) from the African continent over the past four decades, there has been another equally devastating 'secondary brain drain' – not at the level of scholars and scientists but at the level of postgraduate students. Many students in the region do not study in their home country because of the lack of adequate endogenous facilities, expertise, and very often simply (in the case of postgraduate students) because there are no master's or doctoral programs for them to enroll in.

The countries with the highest outbound mobility rates in SSA are Botswana (87%), Namibia (65%), Lesotho (53%), Swaziland (50%), Mauritius (41%), and Zimbabwe (31%). Students from Mozambique tend to go and study in Portugal; students from Mauritius prefer studying in France as first choice. In both cases, South Africa is the second preferred destination. For many other SSA countries, South Africa is one of the top three preferred educational destinations (together with the USA and UK). Many commentators have observed that an increasing number of universities in SSA are now reliant on South Africa and universities in the North for the training of their doctoral students in particular (Mouton, 2010).

If current trends continue apace, the total number of students for the entire African continent could reach between 18 million and 20 million by 2015. The investment required over the 2006–15 period to increase the capacity of current institutions (classrooms, libraries, laboratories, workshops, and lecture halls), establishing new institutions that are better distributed across the territory and improving administrative and teaching materials, is estimated at approximately US$45 billion (in 2006 dollars) for public higher education as a whole, of which US$20 billion is for low-income countries. However, very few countries in Africa have the leeway to increase the public financing of higher education (World Bank, 2010). Besides inadequate physical infrastructure (and lack of funds for sufficient development), the development of appropriate mechanisms for intergenerational learning is also lacking. As the first and second generations of African professors are retiring or nearing retirement, what have been called the third and fourth generations of scholars, including all those who are doing, just completing, or have just completed their PhD training, are likely to be faced with a shortage of qualified mentors within the universities (CODESRIA, 2005).

Research

Social sciences and humanities research within SSA is predominantly practiced within the universities. A few countries have government-funded research institutes devoted to the social sciences (as in the case of the Human Sciences Research Council (HSRC) in South Africa). In addition, there are also some social research institutes and research NGOs in many countries (such as the Institute for Basic Research in Kampala and again many examples in South Africa) that operate outside of the universities. Most of these research institutes and centers are funded through either international agencies or donor organizations with little if any government support. Given these exceptions, social science scholarship is conducted mostly within academic departments in the universities of the region (Mouton, 2010).

However, the inadequacy of funding has limited institutions' ability to offer adequate remuneration or to invest in infrastructure, research facilities, and equipment, thereby hindering overall research capacity. The consequences of this situation are evident when one considers the minimal contribution of African universities to international academic research (World Bank, 2010). It is well known that most African universities have gone through far-reaching changes over the past two decades, not least of which has been the huge increase in student enrollment numbers at the same

time as international and national funding of public universities has declined. This has left many universities and their capacity to undertake scientific research in a very precarious position. This is no less true of social sciences research (Mouton, 2010).

One of the major difficulties that the social sciences in the SSA region had, and still have, to face is fragmentation of activities and of the community of scholars as a whole. This fragmentation was largely, but not exclusively, due to the colonial partitioning of Africa into more than 50 states, most of which are small and economically dependent. Outside North Africa, where Arabization has been a major development in recent years, social science research is mostly conducted in European languages, particularly English, French, and Portuguese. The building of a 'networked community of scholars' therefore required efforts to transcend disciplinary, linguistic, gender, generational, regional, and ideological divisions (Sall, 2010).

The lack of government support for social science research in SSA translates into very little support for research institutes and centers dedicated to the social sciences and humanities whether based at universities or operating effectively as NGOs. Mouton (2010) compiled a list of research centers dedicated to the social sciences in 25 Sub-Saharan countries (excluding South Africa). The list indicates a total of 149 research institutes and centers. However, of these, only 79 (or 53%) had an active web site in June 2009. But having an active web site does not necessarily mean that the web site has current contents. According to Mouton (2010) only 65 (43% of overall total) of these web sites have contents that could be regarded (very charitably) as being recent: a web site was considered as being 'current' when it contained news or listed events at the center for the past 3 years (2007–09) (**Table 2**).

Table 2 Number of social science institutes by country and 'currentness' of web site (excluding South Africa)

Country	*No. of research institutes*	*Active web site June 2009*	*Current*
Kenya	18	13	12
Nigeria	13	11	6
Ghana	18	9	7
Burkino Faso	9	6	3

Source: Mouton, J., 2010. The State of Social Science in Sub-Saharan Africa. 2010 World Social Science Report: Knowledge Divides, Background Paper. International Social Sciences Council.

From a precursory scanning of these web sites, it became clear that the majority of these centers have a small staff (less than 10) and are invariably funded through international donor funding. This means that the majority of these centers are heavily dependent on so-called 'soft' money, which poses a constant threat to their long-term sustainability. With the 'decline' in the number of robust and vibrant university-based research centers, there has been an increase in transnational and regional research networks. One could argue that such networks are emerging as a direct result of the impact of forces of globalization, greater international collaboration, and increased access to the internet. But at the same time, such networks are also filling the 'void' left by strong national research centers (Mouton, 2010).

The following bodies could however be considered as the two most prominent regional social science research organizations on the continent:

- CODESRIA is headquartered in Dakar, Senegal. It was established in 1973 as an independent pan-African research organization primarily focusing on social sciences research in Africa. It is recognized not only as the pioneer African social research organization but also as the apex nongovernmental center of social knowledge production on the continent (Salih and Draman, 2012).

CODESRIA was established out of a desire to contribute to the growth of an independent, pan-African community of scholars engaged in the production of scientific knowledge of the highest quality and of high social relevance. The CODESRIA mandate is being fulfilled through the establishment of a number of research vehicles such as working groups and networks, and the designing and launching of research programs and projects. Some of these programs and projects are conceptualized and implemented as part of a variety of collaborative initiatives (CODESRIA, 2005).

CODESRIA has made considerable efforts to make its research accessible in Africa and internationally through the use of the internet which has been hailed as a success. The other strategy adopted has been to diversify its dissemination outlets through, for example, cooperation with other institutions for dissemination, such as Librairie Clair Afrique (Dakar, Senegal), University Bookshop Makerere (Kampala, Uganda), Editions Cl6 (Yaounde, Cameroon), Kalila wa Dimna (Casablanca, Morocco), and Mosuro/The Book Seller Ltd (lbadan/Lagos, Nigeria). These outlets are diverse in terms of national language (French in Dakar, Cameron, and Morocco and English in Nigeria and Uganda). These efforts have contributed to considerable improvement in dissemination.

Applicants to the research programs are increasingly linguistically diversified beyond Francophone and Anglophone, with increasing numbers of Arabic- and Portuguese-speaking participants in response to CODESRIA's pledge to increase the number of participants from these countries.

While CODESRIA is pan-African, it has ensured subregional (East, West, Central, South, and North) representation in its organs and activities (Secretariat, Executive Committee, Scientific Committee, research program coordinators, and participants) (Salih and Draman, 2012).

- OSSREA is a regional membership-based and donor-supported research and capacity-building organization whose mission is to promote dialogue and interaction between researchers and policy-makers in Eastern and Southern Africa with a view to enhancing the impact of research on policy-making and development planning. OSSREA's head office is located in the Main Campus of Addis Ababa University (AAU), in Addis Ababa, Ethiopia.

Membership is open to all individuals and institutions engaged in teaching and/or research. OSSREA not only engages in interdisciplinary research but also provides research grants to junior and senior scholars based in the region. It also offers training in research methodology. OSSREA operates major projects either independently or in collaboration with other institutions and produces a variety of scholarly publications ranging from its biannual journal to monographs, books, and research reports.

Its constituency is based on membership drawn from social scientists and institutions engaged in teaching and/or research in the social sciences in Eastern and Southern Africa. Currently, there are 21 member countries in the region where OSSREA has National Chapters and Liaison Offices. Institutional membership is open to all institutions, within or outside the region, engaged in the promotion of research in the social sciences in Africa (OSSREA, 2006).

The following section provides a general perspective on the state of social sciences in terms of funding, education, and research structures at country level, by presenting three 'case studies.'

Case Studies

South Africa

The Academy of Science of South Africa (ASSAf) published a report in 2011 on the state of humanities in South Africa. Some of the main findings in the report are: There is a crisis in the humanities reflected in declining student enrollments, falling graduations, and decreasing government funding (in real rands) within institutions of higher learning. The evolution and administration of government policy in the post-apartheid period has systematically benefited science, technology, engineering, and mathematics (the so-called STEM disciplines) to the exclusion and even detriment of the humanities disciplines in the country. The humanities within institutions of higher learning are in a state of intellectual stagnation and, singular innovations notwithstanding, have remained in this moribund condition for more than 15 years. The decline of the humanities has many causes that include government policy and funding, institutional choices and decision-making, school guidance and counseling, and parental and student preferences. The single most important threat to the growth of an intellectually vibrant scholarship in the humanities is the problem of the aging academic and research workforce, a factor that must be read alongside the evidence of a decline in doctoral graduates in the humanities fields (ASSAf, 2011).

Funding

The total income of the public higher education system is usually derived from three sources of funding, namely (1) government funds, which include subsidy (or block grant) amounts and earmarked funds for special purposes; (2) student tuition and all class fees, as well as accommodation or residence fees; and (3) private income such as donations, investment income, and income from contracts/grants for research or the delivery of other services from agencies other than the South African government.

The rates of growth (in nominal rands) of these income sources differed over a 9-year period from 2000 to 2008. Income from government sources increased at an average annual rate of 8.7%, student fees at an average annual rate of 12.2%, and private income at an average annual rate of 14.2%. Total income increased, in nominal rands, by R18.8 billion (or 137%) in the same period. The government funding share of the income total declined from 49% in 2000 to 40% in 2008, a decline that was absorbed equally by student fees and private income.

About 80% of the government higher education budget is allocated to block grant funds that are distributed through a mechanical subsidy formula. These block grants are described as 'council controlled funds' because they can be spent at the discretion of the council of each university. The remaining 20% of the government higher education budget is allocated as earmarked funding for special purposes. These earmarked amounts include at present the National Student Financial Aid Scheme of South Africa, funds for redeveloping the physical infrastructure of the higher education system, and special project funds such as support for foundation training and clinical training grants. Councils have no discretion as far as earmarked funds are concerned: They must ensure these amounts are used only for their designated purposes. The main drivers of the two government funding formulas that operated over the period 1996–2008 have been student enrollments and the classifications of education subject matter.

During the period up to 2004, the funding ratio between science and technology students and humanities students was 2.67 to 1. This ratio dropped when the new funding framework was introduced in full in 2006. In terms of the new framework, the humanities are divided into fields that have a weighting of 1.0 (law, librarianship, psychology, social work/public administration), those that have a weighting of 1.5 (communication, all languages, philosophy/religion, all social sciences), and those that have a weighting of 3.5 (fine and applied arts). The weightings of fields in the science and technology category are spread between those that have a weighting of 1.5 (computer science), those that have a weighting of 2.5 (architecture/planning, engineering, mathematical sciences), and those with a weighting of 3.5 (agriculture, health sciences, life and physical sciences). Because of these changes in weightings, the average funding ratio between science and technology students and humanities students has moved close to 2:1 (ASSAf, 2011).

Besides normal government subsidies, government funding for social sciences research projects is primarily obtained from

the National Research Foundation (NRF). The NRF was established through the NRF Act (Act No. 23 of 1998), following a system-wide review conducted for the Department of Arts, Culture, Science and Technology. The new entity incorporated the functions of the research funding agencies that were previously servicing various sections of the research community, namely the former Centre for Science Development of the HSRC and the former Foundation for Research Development that included several National Research Facilities.

As an independent government agency, the NRF promotes and supports research in all fields of knowledge. It also conducts research and provides access to National Research Facilities. The NRF receives its mandate from the NRF Act (Act No. 23 of 1998). According to Section 3 of the Act, the object of the NRF is to:

- promote and support research: through funding, human resource development, and the provision of the necessary facilities in order;
- facilitate: the creation of knowledge, innovation, and development in all fields of science and technology, including indigenous knowledge, and thereby to
- contribute to: the improvement of the quality of life of all the people of the Republic (NRF, 2014).

As already indicated under the Sub-Saharan section, external funding for social science centers/institutions conducting various research projects is also common and includes funders such as SIDA, DAAD (German Academic Exchange Service), DFID, USAID (United States Agency for International Development), SANPAD (South Africa-Netherlands Research Programme on Alternatives in Development), etc.

Education

Social sciences are primarily taught at the country's 25 universities and generally involve courses such as development studies, languages, philosophy, religion studies, communication, public governance, historical studies, health studies, political sciences, psychology, social work, sociology, and social anthropology.

South Africa began restructuring its higher education system in 2003 to widen access to tertiary education and reset the priorities of the old apartheid-based system. Smaller universities and technikons (polytechnics) were incorporated into larger institutions to form comprehensive universities (South Africa.info, 2012).

In 2011, two reports (The Academy of Science of South Africa (ASSAf)'s report (http://www.assaf.org.za/wp-content/uploads/2011/08/25-July-Final.pdf) and The Charter for the Humanities and Social Sciences Report (http://www.charterforhumanities.co.za/final-charter-report-released)) on the humanities and social sciences (HSS) in South Africa pointed toward the importance of humanities, while indicating certain challenges, including a decline of student enrollment and financial support since the advent of the country's democracy in 1994. Both of these reports called for a type of national structure that could improve the status and standing of the humanities in South Africa by enhancing scholarship, research, and ethical practice in the field, and advising government.

Subsequently, the National Institute for the Humanities and Social Sciences (NIHSS) was formally established in December 2013 as the result of extensive work toward drafting the 2011 Charter for Humanities and Social Sciences.

The overall mandate of the NIHSS is to develop and set up the institutional and logistical framework for the envisioned higher education institution for the HSS. The role of the institute is, broadly, to enhance and support the HSS in South Africa and beyond, and to advise government and civil society on HSS-related matters. It does so through its various programs, including the Catalytic Projects, the Doctoral Schools, and the African Pathways Programme, and through supporting the DHET in the implementation of the proposed corrective interventions.

Further functions of the NIHSS include:

- providing services to the higher education sphere within the HSS;
- advancing learning within its specific scope or application by ensuring collaboration or collaboration of the work of higher education institutions; and
- advising the minister on matters relating to its specific scope or application, or to higher education generally (NIHSS, 2014).

Research

The humanities (including the arts) and social sciences (including economic sciences) constitute approximately 37% of South Africa's total research output when measured in terms of papers in peer-reviewed journals. Two 'publication cultures' exist among South African scholars: Scholars in the humanities publish predominantly in South African journals, while scholars in the natural and health sciences publish much more in foreign journals. There is growing evidence of increased international collaboration resulting in increased 'visibility' of the country's humanities scholarship. The annual number of monographs submitted to DHET for subsidy initially declined but recently seems to have settled at an average of around 60 titles per year. The vast majority of monographs are in the humanities (82%). Scholars in the humanities fields benefit more from the DHET research subsidy scheme as there are many more journals in these fields (compared to the number of journals in the natural and health sciences) included in the list of accredited journals of the DHET. The humanities fields dominate the total number of doctoral graduates produced (47%); within the humanities three fields dominate in the production of the total number of doctorates: education (23.9%), religion (17.3%), and psychology (10.7%) (ASSAf, 2011).

South Africa hosts a few prominent institutes and research centers working in the social sciences fields – most of which are situated at the universities, but some also being independent of larger academic institutions, e.g., Africa Institute of South Africa, Public Affairs Institute, South African Institute of International Affairs, etc.

The most significant national research body focusing on social sciences research is the HSRC – which was established in 1968 as South Africa's statutory research agency and has grown to become the largest dedicated research institute in the social sciences and humanities on the African continent, doing cutting-edge research in areas that are crucial to development.

The council conducts large-scale, policy-relevant, social-scientific research for public sector users, nongovernmental organizations, and international development agencies. Research activities and structures are closely aligned with South Africa's national development priorities. The HSRC's integrated research programs provide single points of entry – complete with a critical mass of researchers – for interdisciplinary and problem-orientated research in the following areas:

- democracy, governance, and service delivery;
- economic performance and development;
- education and skills development;
- social aspects of HIV/AIDS, STIs, and TB;
- human and social development;
- population health, health systems, and innovation.

The organization is home to about 500 staff members, all dedicated to support the conducting of 150–200 projects per year on social science and humanities research. The HSRC has a strong footprint in other African countries through its affiliation with CODESRIA, participation in SADC and NEPAD, as well as hosting African Research Fellows in the organization. The HSRC also has a global presence and has been chosen to host the 2015 World Social Science Forum. The council's research outputs include reports for users, occasional papers, and scholarly articles in peer-reviewed journals, books, and a news magazine that allows us to improve the public understanding of science. These are disseminated in print through the HSRC Press, through policy briefs aimed at government and policy-makers, and through the media, including social media, the HSRC web site, conferences, and extensive research networks (HSRC, 2014).

Democratic Republic of Congo

The DRC faces immense challenges in delivering education services to all persons of school age in the country (OSISA, 2009). The Congolese government hardly delivers governance and public services, not even basic education services to all children of school age. Dictatorship, economic decline, more than a decade's civil war, and endemic corruption have unsurprisingly left an education system and research program that are catastrophically failing the nation's children, with consequences for the national economy. The most typical problem, however, is simply the absence of specific services (USAID, 2012).

Funding

To overcome the country's educational deficit, a massive increase in the education funding or budget will be necessary to pay for the expansion of teacher training, the development and distribution of teaching materials including books, the construction of new schools, and the improvement of the conditions of work for teachers and lecturers, especially those in remote areas of the country. But the Congolese government would have to take action to ensure that funds allocated to the Ministry of Education are being correctly spent and utilized.

Most efforts by the donor agencies have endeavored to solve one aspect of the challenges faced by the Congolese educational system and ignored the others. Whilst being well meaning, these projects such as the Education Management Information System (in French *Système d'information pour la gestion de l'éducation*) have provided little more than superficial gains and little long-lasting impact. (Recently, a computerized Education Management Information System in Congo was installed – within the Ministry of Education, set up as a project funded by the African Development Bank and UNESCO.) In the past there was also a real lack of communication between the various organizations such as UNICEF, UNESCO, and the African Development Bank involved in providing funds and assistance to the education sector of Congo. This lack of systematic long-term donor engagement and intervention has had an adverse impact on the sector since the millions of dollars allocated by the aid agencies have not been effectively or efficiently utilized. Future assistance projects must now find better ways of dealing with the root causes of the poor educational system in the DRC. The sector needs urgent reform to ensure that key role players provide incentives for the continuation of any assistance scheme whilst appealing to the interest of the learners. Only by adopting such an approach will the education sector in the DRC be able to contribute to the Millennium Development Goals of quality and good education for all.

Education

Much of public education, funding, and research development projects are simply provided through mixed arrangements (for instance, the state appoints the teachers, but it often falls to local communities to pool their resources to pay them, build schools, and provide supplies). In addition, the lack of means is a serious impediment to effective governance of the education system in Congo. Whether in the educational system or administration, insufficient funds prevent proper functioning. Things as mundane as office space, stationery, readings, books, desks, chalk, etc., as well as supplies, transportation, telephone units, and the like, are making effective administration and the delivery of a quality education for all often impossible. Therefore, more often than not, teachers and lecturers come to work but are then largely unable to properly fulfill their intended functions.

Furthermore, it must also be emphasized that staff that are entrusted with the management of bursaries and research funds are severely underpaid and often lack the proper qualifications and education necessary to adequately complete such tasks. Teachers and lecturers at all levels of the education system (from primary school to tertiary education) frequently demand bribes from students or pupils in order to pass a class. As women are the most vulnerable group in Congo, lecturers at public universities and teachers of the primary and secondary schools often propose to a learner a sex practice (whether she is brilliant or not), also known locally as 'Points Sexuellement Transmissives' – which can be translated as 'Marks sexually transmission.'

The qualifications of teachers also leave a lot to be desired. A legal framework is in place to govern the recruitment and promotion of workers in the education sector, including the law regulating the civil service generally, and ordinances establishing the education inspectorate, the administration service for pre-primary, primary, and secondary education, and the administrative staff at higher and university level ((1) la loi No. 81-003 du 3 Juillet 1981 portant Statut du Personnel de Carrière des Services de l'Etat; (2) l'ordonnance-loi No. 91-231

du 15 Aout 1991 portant règlement d'administration relatif au corps des inspecteurs de l'enseignement primaire, secondaire, et professionnel, etc.). These laws are generally in compliance with the relevant international standards and establish rules and regulations for nondiscriminatory and competitive recruitment, though they reflect their age in some respects: for example, by not establishing systems to guarantee representation of women among the administrative and teaching staff. More interestingly, the legal rules are practically unknown among those responsible for management of staff in the education sector, and the principles established are routinely ignored in practice.

The general public's lack of knowledge of the right to proper education and of the law in general, exacerbated by a rooted corruption system, constitutes a reason for the poor management of the education system in Congo, and thereafter a lack of implementation of laws and international standards, in line with the new ambition to establish a democratic dispensation in the country. This situation derives in part from the uncertainty of laws, but also from the limited education of many Congolese, including those who serve in official capacity, and the lack of widely available information and civic education.

Training centers exist in principle for both teaching and administrative staff, at school and university level. Examples include the Primary and Secondary Teacher Training Institute (*Institut de formation des cadres de l'enseignement primaire et secondaire*); the National Training Service (*Service national de formation*); in charge of in-service training for existing staff; the National Institute for Professional Training (*Institut national de préparation professionnelle*), responsible for training administrative staff; and the University Pedagogical Serve (*Service de pédagogie universitaire*). But since the withdrawal of donor supports in 1991, these training centers have been paralyzed due to lack of funds and do not fulfill their mandates for initial and continuing training for school teaching and inspectorate staff, a situation that may explain the large percentage of unqualified teachers in the system.

Teaching quality is further compromised by extremely low salaries, which are irregularly paid, subject to problematic provincial and functional disparities. Poor pay is also matched by poor conditions of work and a lack of resources in the schools and universities. Strikes are frequent in the sector as a result, especially at the outset of each academic year. Absenteeism is also a serious problem, with teachers simply failing to turn up to their posts on a regular basis (as a livelihood strategy, most of them in the provinces of mineral-rich areas find themselves as artisanal miners). In addition, it seems that there is minimal enforcement of ethical rules, sanctions are almost never applied even for gross misbehavior, let alone for poor performance, and the codes of conduct exist on paper only. As a result, most schools and universities are run by churches and private mining companies, and parents are expected to pay fees that are usually higher than their income.

Research

The DRC has some of the world's most outdated infrastructure for education, training, and research and development. A lack of detailed information about the distribution of teaching staff in Congolese schools is just one of the results of the generally poor system of information collection and management. However, it is fair to state that government expenditure on teaching and research is extremely low, and, as a result of widespread corruption, officials usually misuse the funds. Even though universities such as Universities of Kinshasa, Lubumbashi, and Kisangani have research centers (mainly in major cities), and schools exist in every city (see **Figure 1**), most of them are old and lack basic resources such as libraries, laboratories for research, and trained teachers.

Finally, the research funding process, appointment of teachers/lecturers, and granting of bursaries (if any available) that are intrinsic to the development/management of the education system are also vulnerable in that the employees of the Ministry of Education are easily manipulated by higher level government officials. Indeed, many of the employees working at the Ministry of Education are hired not on the basis of merit, but on their personal connection to relatives or friends in power. Because of the existing power dynamics, employees at the Ministry of Education also face an impossible situation where they cannot adequately follow normal procedure and regulations in appointing teachers or granting bursaries. Certain employees are paid by applicants under the table as part of an individual's effort to circumvent the process.

To sum up and as outlined above, the education and research development standard in Congo is low, and would require urgent fundamental reforms to spur the country's economic and social development. There is also a need for complete reform of the recruitment, training, and performance review systems for teachers and lecturers to restore a sense of professional pride among staff working in the sector, and ensure that those responsible for teaching the nation's children and youth are properly qualified for the job. Among measures needed in this regard is the revitalization and adequate funding of existing training colleges for teachers.

Ethiopia

Ethiopia is the second most populous country in Africa, next to Nigeria, hosting over 90 million people (CSA, 2007). According to 2011 DHS, Ethiopia has over 80 ethnic groups with diverse social, cultural, and linguistic identities. Although the service sector and industry have been supporting the economy recently, most of the population makes a living out of mixed agriculture. The total land surface is about 1.1 million square kilometers and shares borders with Djibouti, Eritrea, the Republic of the Sudan, the Republic of South Sudan, Kenya, and Somalia (CSA, 2011).

The history of modern formal education in Ethiopia is not more than a century old while informal education has been practiced in Ethiopian Christian religious institutions since the introduction of Christianity in the fourth century (Asgedom, 2005). Informal education in Islamic scholarship institutions has been provided in Ethiopia since 890 AD. In 1908 the first modern school, Menelik II primary school, was established and after 1925 education was recognized by the imperial government as a key tool for development and modernization. The traditional church and Islamic education institutions and scholarships are now competing with the modern educational establishments (Chaillot, 2009; Lule,

Figure 1 State of public schools in a remote area of the DRC – Oriental Province of Congo. Photo by Jean Didier Losango Nzinga, September 2012.

2013b). The government designed sector-specific program action plans in the education sector divided over 5 years in the past two decades (ESDP I–IV) with the intention of decentralization of management and sustaining educational finance (Yigezu, 2013).

Funding

In 1926, the imperial government issued a proclamation to collect 6% tax on all imports and exports reserved a budget to finance education in the country. In 1930, the government instituted the Ministry of Education and Fine Arts, with an additional budget of 2% of the national budget. Primary and secondary education remained free while a cost-sharing mechanism was introduced in 2003 for higher learning institutions.

The government of Ethiopia employs a historical-based budgeting on incremental bases of the previous years of performance, supplemented with the country's economic performance, government revenue, inflation rates, or institutional growth until 2011/12; a program-based budgeting was introduced (MOE, 2010; Yigezu, 2013).

One of the critical steps in financing education was increasing the ratio of the education sector finance against the national budget, which stood at 3.8% in 1995/96 and increased to 13.7% in 1999 under ESDP I. The Ministry of Education increased the budget allocation to over 22.3% of the nation's annual budget in 2012. ESDP IV encourages respective national higher education institutions to involve in generating resources by providing community services, consulting, and need-based training. Among these, higher learning education shared 24.5% (in 2009/10) and 21.4% (in 2012/13) of the education sector budget (MOE, 2005, 2010, 2013).

In terms of financing research from external sources, Ethiopia draws from multiple sources of funding, the same as South Africa, while other African countries pool resources from one, two, or three sources (Jones et al., 2007). The introduction of the long-awaited cost sharing of education intends to relieve the burden of public financing of education, while it partly motivates higher education institutions to have independent sources of funding education (Yigezu, 2013). For the students the costs of education have been free, as well as free nonacademic service, food, lodging, and health services.

Education

Higher learning institutions drive the basic strategic guidance from the nationally mandated Ministry of Education and its affiliate institutions such as the Higher Education Strategic Center and Higher Education Relevance Quality Agency. Higher education institutions in Ethiopia are intended to provide the nation's human capacity in education, research, and community services (FDRE, 2009; Yigezu, 2013).

The social and behavioral sciences in Ethiopia encompass different branches of fields of studies such as anthropology, archaeology, education, indigenous studies, language, political sciences and international relations, business and economics, gender studies, sociology, social work, history, geography, psychology, communication and journalism, philosophy, development studies, African studies, theatrical arts, and peace and security studies.

AAU is the oldest higher educational establishment in Ethiopia. AAU started its operation in 1950 under the name University College of Addis Ababa. It was renamed Haile Selassie I University in 1962 and then Addis Ababa University in 1975.

AAU runs Diploma, Bachelors, MD, DVM, Masters, Specialty Certificate, and PhD degree programs. It launched its first MSc programs in 1979 and its first PhD programs in 1987 (ESSSWA, 1998, 2014).

The expansion and development of higher education has been struggling with the political will as the state is the main financial source of funding for education, research, and community services (Yigezu, 2013). The rapid transformation in higher education in Ethiopia started in 2000 when it shifted from two public universities to 22 in 2010 and currently has 31 fully furnished public universities, with a total student population of over half a million (2012) from less than 5000 in 1996/97, and 31 997 in 2004/05 (MOE, 2010).

Since the turn of the millennium, higher learning institutions witnessed expansion and diversification to ensure equity and open access education in Ethiopia (Yigezu, 2013). The FDRE government in its proclamation 650/2009 reassured higher education institutions with the mandate to programs in regular, extension, distance, virtual, and continuing education. The proclamation further indicated that all the training at higher learning institutions use English as the medium of instruction. Teaching and learning at higher education institutions in Ethiopia is organized according to academic units of colleges, departments, faculties, schools, and institutes. These are independent units leading teaching and research, including developing the curriculum (FDRE, 2009).

In higher learning institutions, curriculum preparation rests on the academic units. The design is to enable citizens with scientific knowledge, independent thinking skills, communication skills, and professional values to also be allowed to receive training in becoming a competent professional. Curriculum development considers in its development the delivery mode to be research and study based, while keeping its content up to date (FDRE, 2009). The common trend in curriculum change or revision is after graduating the first cohort of students admitted to a program (Lule, 2013a).

In 2008/09, the government introduced a guideline on national university intake and preparatory education, especially on admissions to the science and technology, and social sciences and the humanities streams. ESDP IV has a section on determining the student population of higher education, cost sharing, and direction of tertiary education in Ethiopia, based on the recommendation of the ESDP III on relevance of the academic programs. The university intake nationally was regulated so that 30% of the students were placed in the social sciences and humanities while 70% were placed in the fields of science and technology. In 2008/09 the ratio was 52:48 and planned to be 70:30 in science and technology to social sciences and humanities. The ratio has been even more social and human sciences dominant in the earlier years than science and technology fields (MOE, 2005, 2010).

Private higher learning institutions are classified as major stakeholders in education and research. In 2010, the private sector colleges and universities enrolled about 18% of the student population enrolled to higher learning institutions. They are restricted on providing training for teaching staff as of 2005/6 as the government decided to do it through public institutions on grounds of quality. Most of the students in higher learning institutions in the private sector are in social and human sciences (Yigezu, 2013).

Research

Irrespective of the expansion in higher learning institutions in Ethiopia most of the publications until 2007 over a 20-year trend (1987–2007, 517 publications in the science citation index) came from AAU (Mouton, 2010).

In 2009/10 a massive move was made by the government as 13 new universities were inaugurated with a heavy investment in teaching and research facilities such as machinery, laboratories, chemicals, computers, classrooms and office facilities. All facilities highly focused on accessories for science and technology including simple items such as reference books. Among the 22 universities, five are intended to evolve as centers of science and technology (MOE, 2010; Tefera, 2007, 2013).

The current trend in ESDP IV, which will end in 2014/15, focused on consolidating reforms, on system expansion, and on change in governance. This will help improve quality and employability of university graduates, and sustainably develop the research capacity for knowledge creation while technology transfers will be harnessed in priority sectors. It prioritized on diversifying the funding base and mechanism through income-generating schemes and enhancing university industry linkages partnerships (MOE, 2010; Tefera, 2013; Yigezu, 2013).

As a pioneer institution in higher learning education, research, and community services in Ethiopia (social and behavioral sciences included), AAU has instituted a mandated office of the vice president for research and technology transfer (VPRTT). The department is one of the core pillars of the institution mainly in charge of initiating, planning, executing, following up, publishing, and disseminating research along the country's development priorities (AAU, 2013a). The VPRTT in 2013 reorganized institutionally, procedurally guided, and issued regular calls for research funding. These include:

1. national research priority areas funding (AAU, 2013b),
2. thematic research calls for funding (AAU, 2013c),
3. individual small grants research calls (AAU, 2013a),
4. sponsored research projects.

Unlike the earlier years, the VPRTT has conducted consultative meetings with stakeholders on identified research priorities and thematic research issues. Subsequently, the office has published its research manual, research priority areas, and thematic research guides. However, the involvement of the social and behavioral sciences in the thematic research, priority areas, and individual grants is very limited compared with other fields of studies (AAU, 2013b).

The Ministry of Education sets out procedures and strategic directions in education, research, and funding at all levels of education. The higher education institutions have vice presidents for research and technology transfer, who handle thematic research, priority identified research, individual research grants, and small grants for individual researchers based in their respective institutions (AAU, 2013a; JU, 2012).

External funding of research projects is also commonly secured by staff members of the respective institutions in teams and individually. There are stipulated incentive mechanisms for individual staff members who got grants from external sources of finance (JU, 2012).

Organizing annual research conferences for the dissemination of the respective university-wide research and publication

is trending at AAU, University of Gondar, Jimma University, Mekelle University, Bahir Dar University, and Dilla University. The respective academic units are establishing journals to publish their research work at college or university commonly university wide.

Social Science Infrastructure: Asia

Victor R Savage, National University of Singapore, Singapore

© 2015 Elsevier Ltd. All rights reserved.

Abstract

While Asian governments are increasing their budgets for research and development (R&D), most financial outlays are mainly in applied areas in engineering, science, technology, and infrastructural fields. Although the 'soft' areas of R&D in social, cultural, economic, and political sciences have traditionally been relegated to university research centers, they are now gaining traction in private sector institutions and government-backed national think tanks. Given the many challenges Asian communities face (inequality of wealth, poverty, food insecurity, unemployment, domestic political instability, etc.) the importance of social and cultural R&D is likely to grow and become influential in shaping national and geopolitical policies in future.

Introduction

The main English daily in Singapore, *The Straits Times* featured a large advertisement inviting the public to a conference on 'Liveability in Singapore: Social and Behavioral Issues' in February 2014. The conference embodied three uniquely Asian trends in the social services: (1) such themed social conferences are generally rare in Asia compared to science, technology, engineering, and business conferences; (2) they are often organized by universities or national think tanks as the Singapore case (Singapore Management University) shows; and (3) the speakers are generally local nationals of high public visibility (namely Professor Tommy Koh, Laurence Lien, and Gerard Ee), as this conference demonstrates.

In Asia, academic institutions, public think tanks, private research organizations, and multinational corporations have had a relatively recent engagement with research and development (R&D). However, since the post–World War II period, R&D began to develop, and it expanded rapidly in the 1990s onwards. By and large, Asia has played a subservient role in research, science, and technology as compared to West. Over the past 500 years (sixteenth to twentieth centuries), Western science and research have dominated the global intellectual landscape (Gribbin, 2003). Despite earlier mathematical and scientific contributions from the Middle East, South Asia, and China (Arun, 2006), the main research breakthroughs in mathematics, science, and technology have emanated from the West – Europe and North America (Gribbin, 2003).

The overwhelming Western dominance of the global intellectual landscape was the major thrust of Harvard Professor Francis Fukuyama's (1992) thesis, "The End of History." Using a Hegelian historical paradigm, he argued that the West's dominance in all fundamental aspects of intellectual thought (science, technology, and ramifications in politics and social sciences) meant there was no challenge or antithesis, and hence the Western 'scientific thesis' has prevailed. Yet as Asian states rise to power (economically), one wonders whether this emergence will be buttressed by innovative, creative, and entrepreneurial intellectual endeavors in a sustained manner. In the book on *China's Century*, Brahm (2001) clearly missed the importance of intellectual and research contributions in assessing China's economic rise, political reform, and social engineering. In the last decade, however, Asian states have enhanced and expanded R&D. In 2011, Malaysia was home to 73 752 researchers, a threefold increase since 2006 (19 021 researchers), most of whom work in science and technology. Indonesia's Institute of Science (LIPI) consisted of 8000 researchers in 2013. Although focused on the hard sciences, the Institute also conducts research on social issues and history. Recent global studies of secondary school students' academic performance in science, mathematics, and problem solving have demonstrated that Asian students (South Korea, Singapore, Taiwan, Hong Kong, and Japan) are progressing much better than their counterparts in developed Western countries.

Given the quest for economic development in the developing countries through industrialization, R&D in Asia from the 1950s onwards was focused on technology, science, energy, transportation, and infrastructure hardware. Compared to science and technology, in the social and behavioral sciences, R&D assumed a marginal role in government plans and policies. Except for economics and literature, the bias toward the hard sciences is evident in the Nobel Prize categories as well as comparative data in prestigious journals, like *Nature* and *Science*. Yet, one must accept that science and technology is no one-size-fits-all solution to human problems. Feyerabend's (2013) critique of the tyranny of the ideology of science and Sheldrake's (2012) argument of the 'science delusion' are pertinent reminders of why diverse forms of R&D including the humanities and social sciences need to be given weightage for practical and efficient quotidian living. The rapid speed at which cultural changes, political movements, and social transformations are taking place in Asia underscores even more so an understanding of social and behavioral responses to change.

Given the 2012–13 Arab spring, the political turmoil in Thailand, political volatility in India, Bangladesh, and Pakistan, the challenges to hitherto stable ruling governments in Cambodia, Malaysia, and Singapore, and rising disparities of wealth and growing unemployment have all demanded the need for greater social science R&D. What is challenging for academics, politicians, bureaucrats, and corporate titans is trying to decipher, analyze, and comprehend political trends, cultural expectations, social explanations, and economic impacts. This can only be aided by greater investments in R&D in those areas. The Chinese Academy of Social Sciences is already demonstrating the value of such social research when it notes

declining levels of job satisfaction and the falling confidence in social welfare in China (Fenby, 2014: p. 82). In a world in which soft power and smart power (Nye, 2004, 2011) are required to maintain good national and international relationships, the importance of social and behavioral sciences, and the humanities becomes increasingly pertinent.

At a global level, there is also a bias in social science research toward developed countries. The nature of research is thus biased toward strong economies rather than toward developing, weak economies. For example, between 1985 and 2005, of the 76 000 papers in economics, over 36 000 papers focused on the United States – more than the combined papers on Europe, Asia, Latin America, the Middle East, and Africa (*The Economist*, 2014: p. 56).

Drivers of Social R&D

In Asian states, the nature of research funding and institutional R&D has been uneven due to three factors: (1) the general wealth of the country, (2) the level of development of tertiary education, and (3) the economic orientation of national development. Except for the more developed countries and political entities (Japan, South Korea, Taiwan, Hong Kong, and Singapore), the percentage of GDP allocated to research is relatively small: 0.08% in Indonesia, 0.25 in Thailand, and 0.63 in Malaysia. A relatively rich country such as Malaysia had 365 (2006) researchers per million inhabitants compared to Cambodia's 17 (2002). These percentages and figures are even more minuscule when dealing with social and behavioral research. Richer, more dynamic Asian countries (South Korea, Taiwan, China, and Singapore) have, however, increased the number of researchers from 16% in 2003 to 31% in 2007 (R&D Magazine, 2011: p. 30).

In Asian states, the drivers of social, cultural, and behavioral research have been an outcome of four factors and influences, as discussed in the following sections.

Colonial Research Societies: Sociocultural Statements

Historically speaking, colonialism in many ways sets the foundations and institutional base of social and behavioral R&D in Asia. Social science research in Asia was largely pioneered by colonial academic and quasi-academic societies. The British, Dutch, and French colonial powers initiated 'research societies,' which shed light on the culture, language, customs, behavior patterns, religious beliefs, folk medicines, and social practices of the peoples within their Asian colonial territories. Before Western colonies developed universities and higher educational institutions, colonial research societies, supported mainly by colonial civil servants and Western entrepreneurs, pioneered social and cultural research in Asia.

In Britain, the renowned Sanskrit scholar Henry Colebrooke established the *Royal Asiatic Society* (1823) to investigate subjects "for the encouragement of science, literature and the arts in relation to Asia." From its British origins, the Royal Asiatic societies then spread around into India (five subbranches), Sri Lanka, China (Hong Kong, Shanghai, Suzhou, and Beijing), Japan, Korea, and Malaysia. Like their parent society in Britain, each of these affiliated societies established their own journals, which later became the research journals for science, arts, and social issues across Asia. In Malaysia, *The Journal of the Malaysian Branch of the Royal Asiatic Society* (JMBRAS) still continues to publish quasi-academic articles of varied contributors, academics, bureaucrats, and the public. In some ways the development of colonial studies on indigenous cultures, religions, languages, and societies provided the Western academic canon in defining Asia and its cultural diversity. Through the Western cultural filters, Asia became for centuries a cultural antipode for the West (Steadman, 1969), best enshrined in Edward Said's (1994, 1985) 'ism' of 'Orientalism' and it's reverberations in Huntington's (1996) 'Clash of Civilizations,' and Buruma and Avishai's (2005) 'Occidentalism.' Said's thesis and Huntington's 'clash' of East–West cultures provided new impetus in understanding social, economic, and cultural issues in Asia both from Western perspectives and their Asian research centers.

Of the colonial powers, the Dutch were the most active in economic, social, and cultural research both at the 'national' and at the regional–provincial levels in Indonesia. Besides the flora and fauna of the islands, the plethora of Dutch studies on Indonesian societies is unparalleled in other Western colonies. Some of these Dutch scholarly works in social science however were published in English as books and journal articles (Bertram Schrieke; Jacob van Leur; W.F. Wertheim; Justus van der Kroef) (King, 2008). Since most American scholars could not read Dutch, a new wave of studies on Indonesian society was pioneered by American scholars like Clifford Geertz, Karl Pelzer, Margaret Mead, William Withington, Karl Jackson, and Benedict Anderson from the 1950s onwards, putting Indonesia's cultural landscape on the world stage.

National Narratives: Defining Community and State

After World War II, newly independent Asian states embarked on national self-assessments and developmental trajectories to boost nationalistic pride. After centuries of colonialism, many Asian countries desired postcolonial indigenous paths to development and modernization. Interests in indigenous knowledge, vernacular architecture, and folk science underscored postcolonial research agendas in many Asian states. While academics labeled these indigenous social and cultural developments under various other terms (e.g., postcolonial, postmodern, folk science, and indigenous knowledge), former Malaysian Deputy Prime Minister Anwar Ibrahim (1996) referred to these developments in the 1980s as the 'Asian Renaissance.'

Social science research, which underpinned university social science research agendas, was focused on defining nationalistic objectives of new states. However, many current Asian states were initiated and formulated under colonial rule. Benedict Anderson (1991) argued that 'three institutions' (census, the map, and the museum) were invented by the colonial government that shaped the colonial state; with independence all three 'institutions' continued. The taking of population censuses has continued every 10 years in most Asian states (India, Malaysia, and Singapore), albeit intermittently in others (Myanmar), as a means of collecting data on population growth, gender, age, and spatial distribution and the ethnic,

cultural, and religious profiles of citizens. The first comprehensive, Burmese census was conducted in 1931, and the next in 1983 (as an independent state). The Myanmar government in 2014 is conducting the census with the hope of shedding light on its 135 ethnicities (minus the Rohingyas) and the standard of living in the country.

In most countries, the Department of Population Census or National Statistics provides some basic analysis of the census data. However, in most cases, university faculty members make the most use of the data in social science research (economics, sociology, geography, psychology, social work, demography, and political science). In Singapore, the *National Population and Talent Division* is a key generator of population research. Its 2013 White Paper on "A Sustainable Population for a Dynamic Singapore" drew much public criticism for setting its population goal of 6.9 million by 2030. Given India's large population, the International Institute for Population Science does a lot of demography-related research. The Institute completed seven research projects in 2008–09 and has currently 19 ongoing research projects dealing with family health, child health, youth issues, and aging in both villages and urban areas. In Japan, the National Institute of Population and Social Security Research produces population projections and social security surveys especially with regard to Japan's aging population.

The colonial development of museums in the late nineteenth century became institutions defining the historical development of colonially administered societies, communities, and the states. Museums were meant to provide the institutionalized historical narrative of social entities, ethnic groups, and cultural communities, and remained important channels for defining and documenting colonial state histories. State museum narratives, however, provide subjective perspectives, especially when geopolitical conflicts and domestic incumbent governments want such narratives to suit their political agendas. Unlike research materials and publications by academics, museum exhibitions remain, in themselves, national, cultural, and social statements requiring study. In many Asian countries, museums are also sources of research publications (journals, newsletters, monographs, and books).

Maps were drawn to delineate state borders, natural resource locations, transport networks, and the physical geography of states. Mapping was politicized because maps demarcated territories and political jurisdiction. The colonial state utilized maps to define its territories and borders and thus institutionalized the colonial state. Thongchai (1994) provides the best testimony of how maps were used in the colonial period to define expanding British and French territories in Indochina at the expense of Thai national territory. Maps remain a highly contentious issue in defining Asia's many ongoing border wars (China, Japan, South Korea, and Southeast Asian states over the South China seas). Given the geopolitical significance of maps, such research has always been found in strategic institutions in government, defense ministries, and military establishments in India, China, Japan, Malaysia, Indonesia, and Singapore. Maps are visual–graphic expressions of social science data (political and geopolitical representations; economic, social, religious, and cultural issues), which are products of census data, national surveys, or academic research projects.

'Third World' Development Programs

Social science research continued in Asia after the colonial period, supported and abetted by Western institutions in Asia, Europe, and North America. Contributions of the Needham Institute in Cambridge (established in 1948) to understanding the developments of science and technology and social behaviors in China are undeniable (Temple, 1986). Under the vast academic umbrella of development studies, Western scholars expressed their interests in the cultural and behavioral aspects of Asian communities. Governance and labor management were important issues for manufacturing ventures and investments. But the hard sciences took precedence over the soft sciences in universities, polytechnic institutes, and state institutions as industrialization became an important economic driver.

Much of the social science research on Asian societies was carried out in universities and colleges. Universities in the Philippines, India, Indonesia, Malaysia, Myanmar, and Singapore formed faculties of Arts and Social Sciences. Research in sociology, psychology, economics, geography, and political science based on the Western approach was also established. In the social and behavioral sciences, however, Western social science theories, concepts, and models were Eurocentric but they continue to underpin academic thinking in many former Asian colonies.

Asian social research carried out in state and private universities often used Western benchmarks, models, and norms. The Western social systems were often considered the norms and Asian sociocultural representations were often seen as aberrations of the Western models. This was particularly evident in Asian social science research dealing with the pathways to development – where Weberian-type negative logic (e.g., cultural, religious, and social impediments; corruption; old-fashioned customs; and traditions) was often employed in explaining why 'Third World' Asian states could not develop (King, 2008). Western social science theories continued to explain why the developing world remained undeveloped due to psychological factors (McClelland, 1961). According to Austrian economist Erik Reinert (2007), it was David Ricardo's 'comparative advantage' economic concepts, institutionalized in Asia's colonial states, which set back development (weak industrialization and poor R&D) in Asia.

Enter Big Data Analysis

One of the major changes, which augured well for social science research was the breakthrough in the 1990s. Specifically, when IBM entered into statistical machine translation, soon social media like Google and other Internet portals created an explosion of social data. In Indonesia, 'big data' technology is important for large corporations (transnational corporations) where 70% of companies interviewed noted piloting the technology for 2014 (Sudev, 2014: p. 14). In an attempt to make sense of the politically and socially changing landscape, many Asian governments set up research centers to collect, document, organize, analyze, and store national data. With some of the biggest populated countries in the world (China, India, Indonesia, Pakistan, Bangladesh, and the Philippines), big data or "datafication" (Cukier and

Mayer-Schoenberger, 2013: p. 29) will make social science research an easier exercise in the decades to come.

Big data analysis provides three important contributions to social and behavioral R&D: (1) it helps to provide correct social readings of public sentiments, especially when there is evidence that cognitive biases delude us; (2) without big data analysis it is difficult to collect the 'right data' to make sense of public social media issues that tend to be massive, amorphous, uncontrolled, and difficult to read; and (3) in an information society, "data take center stage" (Cukier and Mayer-Schoenberger, 2013: p. 39). Big data allows for bigger samples of information on all aspects of human life. Digitization has transformed data into various purposes, social trends, and other behavioral patterns. In Asia's fledgling democracies, big data has mixed government responses – many governments try to contain Internet searches and muzzle e-mail chatter and blogs. But governments in a new digital age are also interested in establishing national identities, and the net benefits of connectivity provide a better quality of life, economic opportunities, enhanced creativity, and greater efficiency (Schmidt and Cohen, 2014).

The Asian R&D Centers

Traditionally, Asia has in many ways been engaged in social and humanistic research.

Tertiary Institutions

The rise of Asian economies such as Japan, China, India, South Korea, Hong Kong, Singapore, Taiwan, Thailand, Malaysia, Indonesia, and Vietnam since the 1960s has significantly changed the research landscape, enhancing tertiary education and state funding in R&D. Much of Asian research has emanated from tertiary institutions that have grown tremendously over the past three decades. For example, in 2008, Thailand's tertiary landscape included 78 public universities and 89 private higher education institutions with more than 2.2 million students.

The development of R&D in Asia depends in part on the development of tertiary education (universities, polytechnics, colleges, specialized institutions, etc.). Three features undergird tertiary institutions in Asia. Firstly, most Asian countries have universities or colleges that are (1) public (government) funded; (2) privately funded; and (3) overseas universities operating in Asian countries.

The earliest indigenous Asian university is the seventh century Nalanda University in Bihar. Given its historical importance, Nalanda is being reconstructed by India and other Asian countries (China, Thailand, and Singapore) to capture the rise of Asia in the twenty-first century. Under colonial rule, the earliest established university in the Philippines was under Spanish rule in the sixteenth century. Both the indigenous and colonial universities were based on subjects dealing essentially with the humanities, mathematics, languages, and religious studies.

Unlike the West and its emphasis on the 'individual,' in most Asian communities and societies greater attention is given to human nature harmony and social relationships in the family, clan, village, and community (Nisbett, 2003). Asian communities have a long tradition in trying to understand social and behavioral issues as expressed in their philosophies, religious tenets, and folk culture (Peterson, 2001).

One index of top research universities or institutes in Asia is the Nature Publishing Index. Asian research is clearly underrepresented globally – only two of the Asian research centers (Chinese Academy of Sciences and The University of Tokyo) ranked globally within the top 10 in 2013. Based on the number of publications in *Nature* in 2013, Japanese universities make up 50% (5), Chinese universities 30% (3), and Australia and Singapore 10% of the top 10 Asian research institutes or universities. Given that *Nature* publishes both hard and soft (social) science articles, Asian social science researchers can find a global voice; although this is currently lacking.

Asian universities still remain important behavioral and social research centers. Funding generally comes from state governments and in many of the more socialist countries (India, China, Myanmar, Singapore, Cambodia, Lao PDR, and Vietnam), state universities act as research arms of the government. The social and behavioral research areas vary from country to country and over time as well. In the rapidly aging countries and political entities in Asia (e.g., Japan, China, Taiwan, South Korea, Hong Kong, and Singapore) research on aging populations is of prime interest with wide ramifications in health, housing, economic dependence, and mobility. China has a whole research entity dealing with aging: China National Committee on Aging.

Within Asian Universities, several centers have contributed to social and behavioral research. One prevalent research arena lies in Area or Regional Studies (Asian and Southeast Asian Centers) found at the Centre for Asian Studies (University of Hong Kong), Center for Southeast Asian Studies (Kyoto University), Institute of Southeast Asian Studies (Singapore), and Institute of Southeast Asian Studies (Hanoi).

Many universities in Asia have major research centers in broad social, economic, political, and cultural issues. In Malaysia, Universiti Kebangsaan Malaysia (UKM) was established in 1995. The Institute for Malaysian and International Studies looks at policy issues in social transformation and the impacts of globalization on society. Likewise at Seoul National University, The Center for Social Studies undertakes interdisciplinary, social research in new areas on how societies adopt democratization, globalization, and reunification. Many Japanese Universities also have good social science research centers. One of the more recent research centers is Tohoku University's Center for the Study of Social Stratification and Inequality (CSSI) established in 2003, which tackles three key problems: (1) empirical evidence of the extent and types of disparity; (2) looking at theoretical problems and mechanisms of rising disparities; and (3) clarifying the social impact and providing policy recommendations for the impacts.

Private Research Organizations, Nongovernment Organizations

Many Asian research centers that deal with social, strategic, and political policies are either independent or linked to government-funded institutes. These include the Japan Institute of International Affairs (Tokyo, Japan), Atma Jaya Research Centre

(Jakarta, Indonesia), LIPI Jakarta, Centre for Policy Research (Penang, Malaysia), Institute of Philippine Culture (Quezon City, the Philippines), and Institute of Policy Studies (Singapore).

Many private research organizations are on their way to becoming nongovernment organizations (NGOs) with funding from the government and local private institutions or overseas agencies and NGOs. Unfortunately, in many poorer Asian states, government aided research centers, privately-based social and environmental research organizations, and NGOs cannot maintain objective social–cultural interventions.

Among the most important private organizations undertaking increasingly independent social, economic, and environmental research are the Asian Development Bank (Manila, the Philippines), the Mekong River Commission (located in Vientiane, Lao PDR), and the World Bank (Jakarta, Indonesia). In India, the Reserve Bank of India underwrites the Indira Gandhi Institute of Development Research (IGIDR). The IGIDR covers a wide gamut of research agendas in economics, finance, energy and the environment, urban planning, and the social and organizational issues of development. The United Nations also maintains several agencies in Asia, which undertake social and behavioral research. Of all the Asian states, Cambodia, the Philippines, and Thailand are home to the most international aid offices (American, Australian, Canadian, German, Japanese, and Swedish). Nearly all of the 27 United Nations specialized agencies are concentrated in a few Asian countries: Cambodia, India, the Philippines, Korea, Thailand, and Vietnam. These United Nations agencies – the United Nations Economic and Social Commission for Asia and the Pacific, the United Nations Population Fund, the United Nations Project Office on Governance, the United Nations High Commissioner for Refugees, UN-HABITAT, the United Nations Educational, Scientific and Cultural Organization, the United Nations Environment Programme, the United Nations Children's Fund, and the United Nations Institute for Training and Research – undertake national and transnational research programs on demography, food security, poverty reduction, urban issues, housing, and labor.

Government-Linked Research Centers

In many Asian countries, government research organizations undertake important social, cultural, and behavioral research. In Singapore, the Institute of Policy Studies (IPS) conducts research on demography, religion, environment, and surveys on pertinent sociocultural issues and the Institute of Southeast Asian Studies (ISEAS) focuses on political, economic, and sociocultural issues on Southeast Asia and industrial states. In Hong Kong, the Social Sciences Research Centre does considerable government commissioned work. In Vietnam, the National Center for Social Sciences and Humanities of Vietnam (NCSSH) is funded by the government and provides analytic proposals for state foreign and domestic policies. The Center is divided into 16 institutes and seven research centers with 930 researchers. In Indonesia, with its social and cultural complexity, private research organizations are addressing the country's many social challenges. One of the newest research centers founded in 2002 is the Bandung Fe Institute that focuses on interdisciplinary research on complex social science and policy issues.

Japan, India, and China all have well-established government-funded social science research centers that act as important barometers of government programs, thinking, and policies. In Japan, the government-funded Economic and Social Research Institute has a unit dealing with 'Well-Being Studies' that undertakes quality-of-life surveys and measurement of well-being in Japan and some Asia–Pacific countries.

In India, the Indian Council of Social Science Research (ICSSR) established in 1969, conducts a multiplicity of research activities. Besides conducting its own research it funds other research projects, provides technical training, organizes and sponsors workshops, and undertakes publications.

In China there are several research institutes, which concentrate on social and cultural research. The most prominent are the Chinese Academy of Social Sciences (CASS), the Center of Sociological Research and Development Studies of China (CSRDSC), the Center for China Urban and Regional Studies, the Research Center of Tourism Impact Studies, and China's Academy of Social Sciences (CASS). All these research centers operate as umbrella research organizations covering law, culture, sociology, economics, psychology, and even the humanities. CASS is a massive research center with 32 research institutes covering 300 disciplines with 3045 research staff members. In China however, political ideology and leadership visions drive the nature of research agendas: under Mao the four modernizations; under Prime Minister Wen Jiabao correcting and managing the four economic 'un's(unsustainable economy, uncoordinated economy, unbalanced economy, and unstable economy); and under President Xi Jinping the 'China Dream' (peace, development, cooperation, and win–win results).

Contributions of Asian Social and Behavioral Research

Scientific and technological research in Asian institutes and research centers has grown tremendously over the past two decades (since 1995) spurred by Asian governments' applied interests, industrialization policies, urbanization processes, and infrastructural developments. Many Asian countries (Japan, South Korea, Taiwan, China, Hong Kong, and Singapore) embark on emulating developed countries in reserving 2–3% of gross national product development for R&D. However, little of this money is used for social and behavioral research.

In Asia, social and behavioral research is not perceived as prestigious for several reasons. Firstly, scientific and technological research can be compared against international benchmarks for international standards of comparison. Secondly, applied and economic interests exist in science and engineering R&D, which are readily visible over shorter time frames. Thirdly, R&D in science and technology carries an ethos of national modernization and progress for many developing Asian states.

While Asian scholars in science, engineering, and medicine follow the beat of the Western academic drum, Asian intellectuals in the social sciences and humanities are often seen as political icons and social heroes within their own states. The Asian academic voices deal with grounded social research,

which is often critical of government policies. These national voices on social issues from varied universities and local think tanks include in Thailand: Kasian Tejapira, Pasuk Phongpaichit, and Suwinai Pharanawalai; in Indonesia: Budiman, Sjahrir, and Juwono Sudarsono; in Malaysia: K.S. Jomo, Johan Saravanamuttu, and Maznah Mohamad; and in the Philippines: Resil Mojares, Leonor Brionnes, Bernardo Villegas, and Francisco 'Dodong' Nemenzo.

In Asia, of all the social sciences, economics, and business studies seem to command the most academic attention. Given the importance of the economics to employment, Foreign Direct Investments, industrialization, entrepreneurship, productivity, trade, agricultural production, food security, poverty alleviation, and income disparities, economics and business studies remain important research agendas. Two of the best Asian economic icons from Delhi's School of Economics are Amartya Sen and India's former Prime Minister Manmohan Singh.

The massive infrastructural and technological changes are also impacting the social, cultural, political, economic, and environmental landscapes. If one is to sum up the major changes that have profound social, cultural, and behavioral impacts in Asia, five trends can be identified: globalization (information technology) and its local impacts; rapid urbanization; democratization of political systems; environmental issues (such as climate change); and demographic issues due to an aging population. In *The Age of Ecology* (Radkau, 2014), environmental and climate change challenges bring together both science and social science R&D – one needs to know the science behind ecological processes as much as there needs to be an understanding of the impacts of environmental hazards on human culture, environments, and lives. The 2014 Intergovernmental Panel on Climate Change (IPCC) has altered the global community to the challenges arising from sea level rises, droughts, floods, heat waves, and food shortages that urge countries and corporations to spend more finance on environmental and climate change R&D. Unfortunately, climate change impacts remain low priority on many government agendas in Asia (e.g., Bangladesh, Sri Lanka, Pakistan, Laos, Cambodia, Myanmar, the Philippines, and Vietnam) and hence research in these areas is sadly lacking.

All these challenges are, in Ferguson's (2012) view, underpinned by "institutional degeneration" – not only in the Western world but also in Asia as well. The developmental challenges in many Asian states require sound social science knowledge, policy applications, and political management. The Asian Development Bank (ADB) has been proactive in urban and environmental research in Asia and provides interesting research because they are comparative studies, which cut across several Asian countries and cities. In order to develop more grounded, realistic, and applied solutions, universities, corporation, and research centers need to engage in cross-cultural and trans-disciplinary dialogue not only in the social sciences but between the natural and social sciences. In short, there is not only a need for a dialogue of civilizations (Dallmayr, 2002) but also a dialogue between science and the social sciences. This would mean radically changing the impervious silos of disciplinary knowledge in Asian tertiary institutes, and enhancing interdisciplinary exchanges by encouraging social science and behavioral humanities voices to be heard in R&D programs.

Social Science Infrastructure: Central and South America

Cecilia Mabragaña and Maria Beatriz Gavilán, Gerencia de Desarrollo Científico y Tecnológico, Buenos Aires, Argentina

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social science institutions in the region show an evolution from colonialism to e-education in the twenty-first century. Similarities can be traced to a shared historical background, strongly influenced by the Church and stronger or weaker ties to political regimes. During the twentieth century, the social sciences were mainly institutionalized in the national state universities. Thirty-three percent of all degrees and courses offered in the region are in the social sciences, of which the main disciplines include sociology, education, and economics.

Introduction

A broad analysis of the social science institutions in Latin America shows an evolution from colonialism to e-education in the twenty-first century. Similarities and differences can be traced in the historical background, the ties to the political regimes, the late institutionalization within universities, the creation of National Councils of R&T, and the new trends in evaluation and e-learning.

Historical Background

Colonialism

All Latin American countries possess strong institutions for research, education, and communication of the social sciences, but the main infrastructure is found in national universities. There are many similarities among the social science institutions in Latin America but also many differences due to the relatively late institutionalization of the social sciences within the universities, the influence of political regimes and military dictatorships, and differential trends across nations to follow European models. This article focuses more on the similarities than the differences.

The universities in Central America were all products of Spanish colonization and the introduction of the religious orders, especially the Jesuit and Dominican Orders. These Orders and their strong background in education provided the seeds for future universities, the opening of seminaries, and the establishment of religious institutions. The colonies were far from the Spanish motherland, its universities, and its prestigious Catholic seminaries. The young colonies needed trained civilians and ecclesiastic personnel to occupy important positions in local governments.

Many universities were founded during the colonial period, such as the Universidad Autónoma de Santo Domingo, created in 1535 by Papal Bull, and the University of San Carlos in Guatemala, created in 1676 by a Royal Decree of Carlos II of Spain (it is the fourth oldest university in America). These first universities were limited in scope but included social sciences and humanities in the curriculum.

Developments after Independence

The university system in Latin America flourished only after the wars of independence during the nineteenth century. The post-independence era witnessed the reestablishment of many universities whose activities had been interrupted during periods of political upheaval. The scholarship, academies, and universities of Europe and the United States greatly influenced this academic renaissance.

During the twentieth century, the social sciences were mainly institutionalized in national public universities where they could be intertwined with national political concerns and activities. During those years, many national Councils of Science were created to delineate policies and strategies for research and scientific infrastructure. In most Latin American countries, a science council is the principal state agency that funds research, grants scholarships, evaluates programs and projects, coordinates research institutions, and hosts scientific journal portals. CONICET in Argentina, CNPQ in Brazil, and CONACYT in Mexico have their own institutes, but they are closely linked to the national and state universities.

Institutionalization of the Social Sciences

Institutionalization across the Region

While a general trend of institutional consolidation of social science infrastructure took place in the second half of the twentieth century, the process varied according to unique sociopolitical contexts. The influence of democratic regimes versus military dictatorships differed significantly. From the 1930s through the 1960s, Brazil, Uruguay, and Chile consolidated the social sciences in a democratic environment, with political liberties and academic freedom. However, in Argentina, the introduction of social sciences took place only after Juan D. Perón was removed from power. The University of Buenos Aires, the biggest Argentine national university, was granted significant autonomy, and two of the leading representatives were the historian José Luis Romero and the sociologist Gino Germani. There are other examples of nondemocratic governments that did support social sciences, for example, the Mexican government, which although it had a single-party

regime, nevertheless sustained the development of the social sciences with public funds, especially anthropology and sociology.

Though the interaction between the social sciences and national government was very strong in the three largest Latin American countries, Mexico, Brazil, and Argentina, the nature of the interaction varied substantially. For example, military regimes in Uruguay, Argentina, and Brazil were suspicious and disruptive toward academic social science research and organizations in their respective countries, but this paradoxically strengthened independent research centers that received funding from external countries and independent sources. Although a one-party regime, Mexico did not improve its centers with external financing but rather through the migration of Latin American researchers leaving their own countries because of restrictions imposed by the military regimes. Mexico, in fact, received two waves of scientists: the first were Spaniards fleeing the Franco regime; the second were Latin Americans leaving their countries for political reasons. These political frameworks gave way to strong displacements of scientists and weakened research output. During those same periods, there was an intensive expansion of the number of students in social science disciplines, especially in countries that do not have entry quotas, such as Mexico and Argentina.

In these initial periods, there was a consistent influence of external professors, different approaches to social problems, and a very marked influence of political ideologies mixed into the sociological discourse. There was always a strong political connection between high-level social scientists and politicians. In Brazil, for example, two high-level scientists-turned-politicians were Fernando Henrique Cardoso and Ricardo Lagos. Post 1945, the social sciences were also greatly influenced by the Cold War, the Cuban revolution, the proliferation of leftist guerrillas, and the ideas of the Catholic Church, as delineated in the papal encyclical, Rerum Novarum.

Establishment of Chairs and Councils

Academic chairs in sociology and the social sciences were established in all countries by the early twentieth century. The first one was in the School of Philosophy and Letters at the University of Buenos Aires in 1898. This process continued at the Universidad de La Plata, Universidad de Córdoba, and later at the Universidad del Litoral, revealing a trend toward federalization. In 1940, an Institute of Sociology was established at the University of Buenos Aires. In this same year, Chile had established 50 social science chairs. Brazil entered more slowly into this process, but after the establishment of a chair of sociology in the Escola Livre de Sociologia in 1933, the institutionalization of social science expanded throughout Brazil. In Uruguay, the first chair of sociology was created in 1913 and later reestablished in the School of Law.

During this time frame, many interesting studies employed fieldwork methods introduced by independent scientists, and these provided another view of the academic vision of the region's social sciences. In Chile, the studies provided by economic structuralists working in the Comisión Económica para América Latina (CEPAL) were very influential throughout Latin America, and still are today. CEPAL provides Chilean social scientists with many programs, grants, and educational activities, such as Ward and later Durkheim, positivism, the German reconstruction of the spirit of the peoples, and variants of Marxism, which have proved greatly influential.

The Consejo Latinoamericano de Ciencias Sociales (CLACSO), based in Buenos Aires since 1967, had two important leaders in the early period of Latin American social sciences: the economist Aldo Ferrer, an important proponent of economic nationalism; and the engineer Enrique Oteiza, a founding member of CLACSO. CLACSO had (and still has) a strong pan-national role in Latin America and has connected research centers across Latin America. Currently, it is a network of 320 research centers and over 600 graduate programs in the social sciences and humanities.

The Facultad Latinoamericana de Ciencias Sociales (FLACSO) is an international, regional, autonomous organization created by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1957. Its principal objective was and is to establish postgraduate programs in social sciences. It has seven academic units, eight programs, and official academic chairs in Argentina, Brazil, Chile, Costa Rica, Ecuador, El Salvador, Guatemala, Mexico, Panamá, Paraguay, Dominican Republic, and Uruguay. From 1957 to 1973, the only chair was located in Santiago de Chile; it was eventually terminated by the military regime of Augusto Pinochet. The School of Sociology of FLACSO-Chile had many well-known European professors. The first director was a Bolivian sociologist and philosopher, René Zavaleta. FLACSO has been a key influence on the 'Latino Americanization' of the social sciences (i.e., from creating a pan-national Latin American presence in the social sciences to a series of nationally focused social science faculties in various countries).

Internationalization

Institutionalization of the social sciences paralleled internationalization. Many educational missions, exchanges of academics, and visiting professorships were financed and sponsored by UNESCO and also by the Ford Foundation. The first specialized international social science associations were organized in Argentina: in 1950, the Latin American Sociology Association; then in 1960, the Italian sociologist Gino Germani founded the Asociación Argentina de Sociología.

In 1960, FLACSO signed agreements with the Ecole Pratique des Hautes Etudes in Paris, the University of North Carolina, and the University of Chicago. These agreements, along with links to various Jesuit universities, promoted external influence on the development of Latin American social science programs and were instrumental in establishing sociology programs in Brazil, Chile, and Argentina.

In the 1970s and 1980s, the Economic Commission for Latin America (ECLA/CEPAL) tackled two key subjects: development and underdevelopment in what was then called the 'Third World.' Seminal works on these topics were written by scholars such as Raul Prebisch, Celso Furtado, and Gino Germani in Argentina, Florestán Fernandez in Brazil, and Pablo Casanova in Mexico. During this time, the social sciences and many other institutions as well engaged in the discussion of social problems, experiencing a boom in certain

countries: Chile, Peru, Brazil, Argentina, Mexico, and Uruguay. The following is a summary of the institutionalization of the social sciences by country.

Social Sciences in Individual Countries

Mexico

In Mexico, the state and the social sciences have always been related, with weaker or stronger ties. Before the Spanish Conquest, Mexico was home to several major civilizations: Aztecs, Teotihuacanos, Mayas, and Mixteco-Zapotecos. The legacy of highly developed, indigenous civilizations has marked Mexican cultural identity. Though its roots are indigenous, Mexican cultural identity today is mestizo, a mix of local and Spanish influences. The first indigenous president, Benito Juárez, is a great symbol of the Mexican identity and the consolidation of Mexico as a modern nation, especially because he defeated the Hapsburg Empire.

The Mexican social sciences have their roots in the disciplines of history and anthropology. In 1917, the Instituto de Arqueología was founded; in 1929, the Universidad Nacional de Mexico became autonomous; and in 1939, the Instituto de Investigaciones Sociales and the Revista Mexicana de Sociología of Lucio Mendieta were created. Manuel Gamio was another pioneer of the social sciences; he carried out two major projects on the exploration of the archaeological site of Teotihuacán, and on the migration of Mexicans to the United States. At the beginning of the twentieth century, northward migrations were the focus of many sociological studies, and still are today.

The Mexican government founded the Instituto Nacional de Antropología e Historia (INAH) in 1939, as a key piece in the process of institutionalization. Today, the most important Mexican social science institutions are financed by the state. The Social Sciences Institute of the National Autonomous University of Mexico (ISSUNAM) was also founded in 1939, providing a framework for social research in Mexico. ISSUNAM facilitates research on a wide variety of subjects, such as agrarian labor, labor conflicts, indigenous marginalization, and politics. La Casa de España (later COLMEX), established in 1939, provided a space for Spanish intellectuals fleeing the Franco regime. It became a solid cultural center with full-time academics and many prominent intellectuals who published in the serial collection Las Jornadas de el Centro de Estudios Sociales de el Colegio de Mexico: José Medina, Octavio Paz, Raúl Prebisch, Kingsley Davis, among others. This Centro de Estudios Sociales (CES) was closed in 1946. In the late 1930s, Daniel Cosío launched the publishing house Fondo de Cultura Económica, which provided translations of all the fundamental works of Pareto, Durkheim, Weber, Keynes, Marx, and others. Today it depends on the federal government for support, but its editorial policy is totally independent.

Many exiled scientists stayed in Mexico, as happened with the Argentine exiles from the military regimes. The construction of the Universidad Nacional Autónoma de México (UNAM) campus, a big architectural undertaking funded by the state, began in 1947, bringing together all the schools, which today number more than 150 000 students and 30 000 professors. These three institutions, COLMEX, UNAM (ISSUNAM), and INAH, are the backbone of the social sciences in Mexico.

Professors began teaching sociology only in the 1960s. From 1965 to 1970, the publication of the book *La Democracia en Mexico* by Pablo González Casanova stimulated studies on the social problems of poverty, political power, and inequality affecting Mexican society. In 1967, the master's degree programs in sociology and political science opened in UNAM. After 1970, the increase in the number of PhDs was exponential. Between 1951 and 1979, the number of sociology students grew from 3 to 7000. This boom in registration was attributed to the commonly held belief that sociology would bring about (positive) structural changes. After this period of euphoria, in the 1990s, interest in these fields declined and students switched to economics and econometrics. The decentralization of COLMEX initiated the foundation of the Colegio de Michoacán and the Colegio de la Frontera Norte in Tijuana.

In the 1970s, Mexican students from all over the country that used to attend UNAM dispersed among 32 state universities. While the lack of professors was a problem, the new waves of exiles from Argentina and Chile contributed to university development. The 1971 creation of the Consejo Nacional de Ciencia y Tecnología (CONACYT) contributed to scholarship abroad and the overall supervision and support of all activity in research and technology.

As a discipline, anthropology did not receive the same rank or prestige as sociology and political science. Despite the fact that 10% of the Mexican population is of indigenous descent, anthropology has not been the focus of academic research and actually lost some of its importance in scientific terms.

Higher education in modern Mexico is a consequence of public policies and funds in spite of crises and political upheavals. Ten percent of the graduate students in Mexico opt for the social sciences.

Today, UNAM is the best-ranked university of Mexico (70) (Webometrics Ranking of World Universities – CSIC España 2013–14) and home to over 320 000 students.

Nicaragua

Nicaragua has over 50 universities, national and private. The oldest is the Universidad Nacional de Nicaragua (UNAN), founded in 1812 in the city of León. The Recinto Universitario Rubén Darío opened in 1969. Education, economics, and humanities departments were developed at the Managua campus. During the decade of the Sandinista revolution, the University of Managua grew in strength, number of students, and resources. In 1982, UNAN-Managua became fully independent from the León historical headquarters. Nicaragua is now a part of the Sistema Centroamericano de Evaluación y Acreditación de Educación Superior (SICEVAES).

Nicaragua offers a range of 194 degrees in the social sciences, all at the Instituto Nicaragüense de Investigaciones Económicas y Sociales (INIES). The university system offers several postdoctoral degrees: 10 in education and languages; 7 in business administration and economics; and 5 in the humanities, law, and social sciences. Two doctoral programs are offered jointly with the Universidad de Zulia, Venezuela, one in social sciences and one in economics.

Guatemala

The University San Carlos de Guatemala, founded in 1676 by a Royal Charter of Carlos III of Spain, is one of the oldest universities in Latin America. After Guatemala's independence from Spain, the university's activities were interrupted. Today this public university has 33 campuses, 10 schools, and other institutes, and offers eight postdoctoral programs.

Honduras

The most important university in Honduras is the Universidad Autónoma de Honduras (UNAH), which has campuses and schools in 11 provinces. There are also more than 30 private universities. The university system offers a total of 258 degrees, 81 in the social sciences. A doctorate in Comunicación y Desarrollo (Communication and Development) is offered jointly with the Universidad Complutense de Madrid. With the sponsorship of Andalucía, Spain, a special digital library was created for the study of migration and intercultural relations.

El Salvador

The first Salvadorian university was founded in 1841 in a struggle to gain independence from the prestigious Guatemalan University of San Carlos. Until 1967, it was the only university in the country. Lacking the professionals needed for its development, the university encouraged the professional characteristics of the Napoleonic model.

In 1944, the university changed its goals, giving priority to research, academic excellence, and library development. In 1972, military intervention ended this 'golden era,' but in 1992 an era of reconstruction began. Today there are 37 public and private universities in El Salvador, and more students attend private than public universities. Of the 258 degrees offered, 139 are in the social sciences. REDISAL is the network of Salvadoran researchers. The National Center of Research in the Social Sciences (CENICSH) was created in 2009. Universities are publically funded; the social sciences receive the largest proportion of funds (31%), followed by engineering and technology (28%), natural and exact sciences (17%), medicine and health care (12%), humanities (8%), and agronomy sciences (4%).

The Consejo Nacional de Ciencia y Tecnología (CONACYT) was created in 1992 as a decentralized, autonomous institution and the chief authority for all aspects of science and technology. It includes the registration of all Salvadorian researchers and has a Center for Technological Information. It promotes different types of scholarship cofinanced by UNESCO and the governments of Mexico, Japan (Monbukagakusho), and Germany (DAAD).

Costa Rica

The first university in Costa Rica goes back to the Casa de Enseñanza Santo Tomas founded in 1814. Political motivations closed the university in 1859, but the schools of law and agronomy still remained open. In 1940, the university reestablished itself as the Universidad Santo Tomas. Today it has seven regional campuses, 41 000 students, nearly 7000 full-time professors, 4000 postdoctoral students, and 600 doctoral students. The university has 13 schools of different disciplines; 30 research centers, of which six are of the social sciences; and 12 institutes, five of which are of the social sciences. The university is also home to the publication portals Latindex and SciELO.cr. Today, Costa Rica is home to 10 public and 51 private universities. The University of Costa Rica is the best-ranked university in Central America, especially in the social sciences, and it has schools of law, economics, education, and psychology. The university system offers 759 degrees, 222 of which are in the social sciences.

Panama

The Universidad de Panamá was created in 1935. The first campus was built in 1947, and 17 buildings were added between 1970 and 1989. Since then, many additional buildings have been added, and regional campuses were opened in different provinces. The Universidad de Panamá has 18 schools, seven of them in the social sciences. The governments of Mexico and France today cofinance Panamanian social science projects. Today Panama has three public and 19 private universities, and the Sistema de Internalización de la Educación Superior Centroamericana (SIESCA) fosters mobility and exchange of fellows and researchers. The total number of degrees is 819, with 287 of them in the social sciences.

Venezuela

Venezuela's best-ranked and oldest university is the Universidad de los Andes. It dates to 1785, when the Bishop of Mérida created an institute for young seminarians; King Carlos IV of Spain accredited it in 1806; and then in 1810, it was given the title of Real Universidad de San Buenaventura de Mérida de los Caballeros. The university was later completely destroyed by an earthquake, moved to Maracaibo, and then reinstalled in Mérida in 1824 as Universidad de Mérida. In 1905, after many closures and reopenings, its name was finally changed to the Universidad de los Andes. Currently, the Universidad de los Andes has two postdoctoral degrees in economics and statistics. Venezuela today has 25 public universities (some with regional campuses) and 27 private ones. The public universities are divided into autónomas (5) and experimental (20).

Dominican Republic

The first Latin American university, the Universidad Autónoma de Santo Domingo, was created by Pope Paul III per Papal Bull in 1538 and ruled by the Dominican Order. Following the Haitian invasion and recolonization period, in 1859 it was reformed along the lines of the European medieval academies, with four faculties (philosophy, law, medicine, and sacred letters). After many closures, reopenings, and 31 years of the Trujillo dictatorship, the university permanently reopened in 1964.

The proliferation of private universities and the opening of regional campuses can be explained by the aforementioned political crises. The best-ranked university is Universidad de Psicología Industrial Dominicana (UPID) and is a private university. The best-ranked public universities are Universidad

Autónoma de Santo Domingo, which has 19 campuses. One of the four public universities is the Facultad Latinoamericana de Ciencias Sociales (FLACSO).

Bolivia

The Universidad Mayor Real y Pontificia de San Francisco Xavier de Chuquisaca in Sucre was founded in 1624 and is the oldest Bolivian university. Founded by a Jesuit priest and expanded in 1775 to include the Academia Carolina, the university was initially dedicated to legal studies. Other universities were also created to train lawyers, and only after several decades and the expulsion of the Jesuit Order did the universities grow to include other disciplines.

The Academia Carolina was the most important university in colonial times and greatly influenced the regions of el Alto Peru and Río de La Plata. Eventually, the academy planted the seeds for the emancipation processes in Latin America by shaping leaders such as Mariano Moreno, Bernardo Monteagudo, and Juan José Castelli of Argentina; Manuel Rodriguez Quiroga of Ecuador; Mariano Alejo Alvarez of Peru; and Jaime de Zaldañez of Uruguay.

Two elements characterize Bolivian universities: university autonomy and the co-government of professors and students. In 1967, the structure and evaluation systems were modified, including the opening of private universities to reduce student overcrowding. Today Bolivia has 16 public universities and 33 private ones. The best-ranked university is the Universidad Mayor de San Simon. Future goals include the improvement of postdoctoral studies and development of research structures in all disciplines.

Peru

Peru is home to one of the first universities in Latin America, the Universidad Nacional de San Marcos. Founded in 1551 by the Dominican Order, the university was granted the support of King Charles V of Spain. It is the only university in Latin America with uninterrupted activity; since its creation, 223 deans have passed through its doors. Today it offers 62 degrees in 20 schools.

There are 35 state universities and 56 private ones. The best-ranked university is the Pontificia Universidad Católica del Perú (891), a private university in Lima established in 1917 with two faculties: school of law and school of letters. The Centro de Investigaciones Sociológicas, Económicas, Políticas y Antropológicas (CISEPA) is one of the university's strongest institutes, with 57 research projects and 237 researchers. The Universidad Nacional de San Marcos has 3360 professors, 672 of them in the social sciences. The Consejo Nacional de Ciencia, Tecnología e Innovación Tecnológica (CONCYTEC) is the governing body of the national system of science, technology, and innovation; it is composed of the academy, the public research system, business organizations, and civil representatives.

Ecuador

Founded in 1946 by the Jesuit Order and the Archbishop of Quito, the Universidad Católica del Ecuador (PUCE) is Ecuador's best-ranked and oldest private university. Currently, Ecuador is home to 54 universities, of which 34 are state universities. The Council of Evaluation, Accreditation and Excellence of Higher Education evaluated and ranked the national universities in four categories according to academy, academic proficiency, research, and organization and infrastructure. Five universities are graded A, 23 graded B, 18 graded C, and 8 graded D. The future challenge for the authorities is to include Ecuadorian universities among the first 1000 universities in the international rankings.

Paraguay

Created in 1889, the Universidad Nacional de Asunción is Paraguay's oldest university. Also the best ranked (3034), the university consists of three schools: law and social sciences, medicine, and mathematics. From 1961 to 2013, 45 new private universities were founded. Today, la Universidad Nacional de Asunción has 12 schools and 2 institutes, offering 74 degrees to more than 40 000 students.

The Consejo Nacional de Ciencia y Tecnología (CONACYT) was created in 1997 as a public, autonomous institution. It is designed to plan, coordinate, and execute the priorities and policies of the National System of Science and Technology. Starting in 2006, the first international project with the support of Programa de las Naciones Unidas para el Desarrollo (PNUD) and Banco Interamericano de Desarrollo (BID) took place. It is steering the creation of a Researcher's Registry and supporting science (scholarships and programs) with a fixed percentage from the general national budget. Paraguay has 300 000 students, 81 percent of which are enrolled at private universities.

Colombia

Created in 1867, the Universidad Nacional de Colombia can trace its origins back to the independence era when its campuses spanned the colonial region of Gran Colombia, across Bogota, Caracas, and Quito. In 1867, the university consisted of six faculties: law, medicine, engineering, art, literature, and philosophy. University facilities also included the Astronomical Observatory, the National Museum, laboratories, the National Library, and two hospitals. By 1940, it offered 20 professional degrees, and between 1973 and 1986, many new graduate programs were created.

There are more than 32 state universities and over 100 private ones. The three best-ranked universities are the Universidad Nacional de Colombia, Universidad de los Andes Colombia, and Universidad de Antioquia. COLCIENCIAS is today the administrative Department of Science, Technology and Innovation. It coordinates the national system of Science and Technology and the Scienti Database (Colombian researchers). COLCIENCIAS also maintains PUBLINDEX for the categorization and evaluation of Colombian scientific journals.

Uruguay

The Universidad de la República was created in 1849. In its first years, it had four schools: medicine, law, natural sciences, and theology. During the first 40 years, there were successive conflicts with the government, and the influence of the Church

diminished. A second stage, which lasted until 1908, gave rise to the modern university, with different interventions and reforms according to the political party in power.

The Universidad de la República established the School of Humanities and Sciences and the Instituto de Economía in 1963. The influence of FLACSO in 1969 was crucial for the establishment of a bachelor's degree in sociology (1970). However, the military dictatorship prevented further development of the sociology department until after 1985.

The Faculty of Social Sciences was created in 1991, the Faculty of Psychology in 1994, and the Faculty of Communication and Information in 2005. There are six state universities and 21 private ones.

Uruguay has separate institutions supporting science and technology. Since 2006, the Agencia Nacional de Investigación e Innovación (ANII) has funded innovation in science and set strategic goals and programs in science policy: funds for research projects, incentives for innovation in business and commercial organizations, scholarships, the national registry of researchers, and the Portal Timbó (access to scientific publications). The Consejo Nacional de Innovación, Ciencia y Tecnología was also founded in 2006 as an expert body on science and technology for the executive government.

Chile

The oldest university is the Universidad de Chile, created in 1842; this was a landmark creation of the young republic. At first tied to the Catholic Church, its first dean was Dr. Andrés Bello, the Venezuelan humanist and aide to Simón Bolivar. Dr. Andrés Bello prepared the founding documents for the creation of the university as a state, secular, and public university. During the first decades of the twentieth century, the most prominent men of Chile passed attended the university. In 1950, the status of full-time professor was extended to all faculties. Today, the Universidad de Chile has about 27 000 students and 3000 professors.

FLACSO, CEPAL, and the Universidad Católica de Chile established the School of Sociology and the School of Economics in 1958. Two key subjects influenced and tackled by CEPAL in Chile during the 1970s and 1980s were development and underdevelopment and the concept of Third World countries.

The Comisión Nacional Científica y Tecnológica (CONICYT) was established in 1967 under the wing of the Ministry of Education. CONICYT supports research and promotes partnerships and scholarships; it hosts the SciELO.cl Program, the National Repository projects, and a network of researchers. Special emphasis has been given to women's studies.

Chile has 16 state and 49 private universities, and 10 research centers. The Universidad de Chile is the best-ranked university (297) together with the Pontificia Universidad Católica de Chile (608). CONICYT Chile will finance 22 new projects to attract Chilean researchers abroad (Programa de Atracción e Inserción de Capital Humano Avanzado PAI). These new projects are predominantly directed to Chilean researchers from the University of Pittsburgh and Johns Hopkins University in the United States, among other institutions.

Brazil

As in most Latin American countries, the origins of institutionalization of the social sciences date back to the legal and social programs of European positivism and the adoption of European and American standards. The study of sociology was initially fostered by the founding of the Scola Livre de Sociologia e Politica in 1934 and the Universidad de Sao Paulo (USP) in 1935, which provided an institutional framework for the social sciences and academic exchange with foreign professors from France, the United States, and Germany. In 1932, the Church turned its Instituto Católico de Estudos Superiores into the Faculdade de Filosofia das Faculdades Católicas, and then in 1946, founded the first Pontifícia Universidade Católica (PUC).

The Sao Paulo School of Sociology was established in 1955. The first master's program in the USP was offered in 1953. Between 1950 and 1960, a number of new institutions were created in Rio de Janeiro. Until the military coup in 1964, the hierarchy of disciplines was dominated by sociology. The importance of anthropology grew in Bahia, Recife, and cultural anthropology with Gilberto Freire in Parà. In addition, important results of anthropological research were displayed at the Goeldi Museum in Belém.

From 1965 to 1983 (until the end of the military dictatorship), social sciences expanded throughout the territory as a result of the establishment of universities, graduate programs, and research. There was also a strong internationalization and implementation of exchange programs with the support of government policies and funding agencies.

The USP model became the university standard and was reproduced in the federal system until 1960. A noteworthy change occurred in 1968 when the university law program modernized, inspired by the American model and influenced by the agreement between the Ministry of Education and Culture of Brazil and the US Agency for International Development (USAID). Scientific investigation was strongly concentrated in the universities and received a significant flow of resources from the government, including the social sciences. Founded in 1951, the Conselho Nacional de Desenvolvimento Cientifico e Tecnologico (CNPQ) is an important funding agency and supports exchange programs and other activities such as the platform LATTES that contains the biographies of all Brazilian researchers and professors.

The social sciences in Brazil's universities expanded dramatically in the 1970s and 1980s; their strength was the graduate programs: masters and doctoral programs doubled enrollment between 1974 and 1985, involving around 7000 scientists. The following are some of the most well-known themes, topics, and authors in the field of anthropology:

- Violence and Crime; Indigenous Ethnology: Alba Zaluar Vivarios de Castro, Carneiro da Cunha.
- Life style of the middle class, cultural habits, violence and drug abuse: Darcy Ribeiro, Cardoso de Oliveira, Amorim, Gilberto Velho.
- Comparative anthropological perspectives: Cardoso de Oliveira and Guillermo Ruben Peirano.

Another strong academic area is ethnicity, which was discussed mainly by Schwarcz, Carneiro da Cunha, and Pinto.

In sociology there are two classical fields of study: social classes and social mobility, pioneered by Guimaraes Valle Silva. Foreign institutions provided funding and the exchange of professors, particularly the Ford Foundation, which sponsored studies of gender, and race and ethnicity from 1960 to 1983. Currently, the Coordenaçao de Aperfeiçoamento de pessoal de Nível Superior (CAPES) has diversified participation in funding scholarships through its exchange programs with several countries, like the Santos Dumont agreement for Brazilian and French graduate programs.

Argentina

The University of Cordoba was the first university in Argentina, founded in 1631, which at that time was a province of the Virreynato del Perú, and later in 1776 was already part of the Virreynato del Rio de la Plata. All the historic, colonial universities were linked to the Jesuit and Franciscan Orders of the Catholic Church. For example, the governor of Buenos Aires founded the Universidad de Buenos Aires (UBA) in 1821. Its first dean was a priest, Antonio Saenz.

The process of institutionalization of the social sciences in Argentina has been marked by discontinuities due to political changes and military coups. These struggles also coincided with the establishment of the private universities. Political confrontations between students and professors and differences in disciplinary orientation were often the source of destructive conflicts.

Argentina's first university program in sociology was created in 1957, rooted in the Peronist movement and tied to the military dictatorship. The first chair of sociology in Latin America was established in 1889 in the Facultad de Filosofía y Letras of the Universidad de Buenos Aires (UBA). In 1918, a massive student strike at the University of San Carlos en Córdoba initiated the historic, autonomist movement across the Latin American continent: Manifiesto Liminar de la Juventud argentina a todos los Hombres Libres de Sudamérica. The chronology of the period can be divided into three periods with distinctive characteristics. The first period (1955–1966) began with a military coup against the Peronist government, which incited political repression and armed struggles. In the UBA there was an intense flux of foreign capital incentivizing research and academic activities. In 1955, the universities were taken over by the military government. Between 1957 and 1966, several undergraduate programs were established in different national and private universities with formal chairs of sociology, anthropology, and political science. The military coup in 1966 resulted in nearly 1000 professors resigning from the UBA and other national universities, especially in the social sciences. During those years, two important research centers were established: the Instituto de Desarrollo Económico (1958) and the Centro de Sociología Comparada (1963), as well as journals associated with them, Desarrollo Económico and the Revista Latinoamericana de Ciencias Sociales. Two publishing houses were important for the diffusion and legitimization of the social sciences: Paidós and Eudeba, the University Press of the University of Buenos Aires.

The Consejo Nacional de Investigaciones Científicas y Tecnicas (CONICET) was created in 1958 and governed by President Bernardo Houssay (Nobel Prize in Physiology or Medicine 1947). CONICET is an autarchic organization in charge of promoting science and technology across public and private sectors. It currently has more than 180 centers of research and its own degree researchers and professionals.

The period from 1966 to 1983 was marked by military coups, political repression, and social struggles. In 1979, an MA program was created with majors in sociology, political science, and education. This time period saw the establishment of independent training centers sponsored and supported by the Ford Foundation, the Swedish agency SAREC, and French agencies. Some of these centers are today part of CONICET's Institutes: Centro de Estudios e Investigaciones Laborales (CEIL) and Centro de Estudios Urbanos y Regionales (CEUR). These centers covered different thematic areas, like rural sociology, labor, and demographic issues. The creation of national universities in the interior of the country that included social science programs grew in number and scope. These new centers produced an interconnected system of researchers and ideas. CLACSO played a decisive role in the network of people and knowledge.

The third period (1983–2003) opened an era of constitutional governments and the reconstruction of universities. Although the economic situation had its ups and downs, questions and themes such as unemployment, poverty, crime, and corruption were and remain central problems and concerns for Argentine social scientists. A new school (Facultad) was created in the UBA that included the fields of sociology, political science, labor, and social work. Social science students represent 40% of the total enrollment. The Ministry of Education established a special agency for the evaluation of graduate courses and programs (CONEAU). The revitalization of the national universities paralleled the diminishing support and funding by foreign agencies.

The Universidad de Buenos Aires is the best-ranked university of Argentina, home to over 320 000 students. It is one of Latin America's largest universities, together with Mexico's UNAM. It has collaborative research projects and programs with other international universities and less developed ones with industry partners. There are no tuition fees, as in all public state universities in Argentina.

Argentina has suffered brain drain for the last 40 years, especially since 1966. After 1983, the brain drain was driven by financial and/or economic reasons. A large percentage of exiles have returned or kept close ties to the countries and institutions in which they worked, obtaining financial support for collaborative studies. The advent of information technologies and the Internet opened new possibilities for the development of networks and reestablishment in local research centers. The 820 researchers who returned to Argentina in 2012 represent 13% of Argentine researchers abroad (estimated at 6000).

FLACSO has proven a very important source for graduate programs in Mexico and Ecuador, and some foreign universities like de Università di Bologna and New York University have established branches in Argentina.

At present, CONICET has over 180 institutes and centers of research, of which 13% concentrate on the social sciences and humanities. From the total number of researchers in the different categories, 18% work in the social sciences.

Dissemination and Communication of Social Sciences in Latin America

Latin America has been a pioneer in organizing interdisciplinary, open access scientific journal portals. The first effort was a cooperative decentralized network of national scientific organizations: LATINDEX (Sistema Regional de Información en línea para revistas científicas de América Latina, Caribe, España y Portugal), which includes scientific journals of the region with approved common quality criteria hosted and run by UNAM, Mexico. Of the 22 295 journals, 10 567 belong to the social sciences.

Another important medium for dissemination is SciELO.org (Scientific Electronic Library Online). Established in 1998 in BIREME (Brazil), the journals included are selected by national scientific organizations. As of 2013, the library has 10 148 journals and over 10 000 000 citations; 226 are social science journals.

REDALYC (Red de Revistas Científicas de América Latina, el Caribe, España y Portugal) is a multidisciplinary open access journal portal, originally and predominantly dedicated to the social sciences and the humanities; it was developed in 2002 through a research program in UNAM, Mexico.

Distribution of Centers and Universities in Latin America

Latin America has 3745 centers of higher education, of which 2226 offer degrees in social sciences (Webometrics and QS Top University – Worldwide University Ranking 2013). The highest concentration is in Mexico (37%) followed by Brazil (13%) and Colombia (13%). Thus, Mexico, Brazil, and Colombia possess 65% of all centers of higher education in the region. These values correlate with the overall population structure. The second largest concentration of universities (25%) in the region can be found in Argentina (7%), Peru (7%), Chile (4%), and Venezuela (4%). Uruguay, Paraguay, Bolivia, Ecuador, El Salvador, Honduras, Nicaragua, Panama, and Dominican Republic account for the remaining 13%.

According to UNIVERSIA, the 1299 universities offering degrees in social science show a similar distribution. According to the QS Top University – Worldwide University Ranking 2013 selection, a ranking system for the 200 most important universities by discipline, only 14 Latin American universities are included, representing 7.5% in 38 subjects.

The analysis of degrees and doctoral courses is based on the ranking established by Q's in the table below. The higher quality and excellence is (1) Q numbers from 1 to 50; (2) Q 51 to 100 (median value); (3) Q 101 to 150; and (4) Q 151 to 200. The last quartile represents the lowest quality of the top 200 universities.

Brazil presents the following excellence structure and scale:

1. Q1/50 = 2 courses. Statistics (USP) and Education (USP)
2. Q51/100 = 7 courses. 2 Statistics (UNICAMP, UFRJ), 2 Economics (USP, FGV), 1 Education (UNICAMP), 1 Political Science (USP), 1 Law (USP)
3. Q101/150 = 13 courses. 6 Sociology (USP; UNICAMP, UFRG, UFRGS, UFB, UFMG), 1 Statistics (UFMG), 2 Education (UFRG, UFRGS), 2 Economics (UNICAMP, PUC RIO), 1 Political Science (FGV), 1 Communication and Media (UFRJ)
4. Q151/200 = 2 courses. 1 Political Science (PUC RIO), 1 Communication and Media (UFMG)

This distribution shows that values are concentrated in the median (7 + 13 = 20 courses out of 24)

Chile, with 4 universities and 7 courses, has the following structure and ranking:

1. Q1/50 = 1 course. Education (PUC-Chile)
2. Q51/100 = 3 courses. 1 Education (UCH), 1 Economics (PUC-Chile), 1 Law (UCH)
3. Q101/150 = 1 course. Political Science (PUC-Chile)
4. Q151/200 = 2 courses. Law (UDP, PUC-Valparaiso)

It is interesting to point out that Chile surpasses Argentina and Colombia in universities and courses. Argentina (UBA) has 2 courses in Q2 and Colombia (Universidad de los Andes) 1 course in Economics in Q3.

Mexico is represented with 1 university and 4 courses, 2 in Q1 and 2 in Q3.

Degrees and Postdoctoral Courses

Latin America is represented by 34 939 degrees and courses, of which 11 722 (33.5%) are in the social sciences (Data: December 2013).

Country	*All degrees*	*Social sciences*
Brazil	9205	3086
Argentina	4725	1534
Mexico	5070	1778
Chile	3340	899
Colombia	3480	1278
Uruguay	707	254
Peru	1829	660
Panamá	819	287
Bolivia	572	172
Costa Rica	757	222
Ecuador	865	365
El Salvador	415	139
Honduras	258	81
Nicaragua	462	194
Paraguay	350	121
Dominican Republic	587	213
Venezuela	1498	439
	34939	11722

Grouping the countries according to the prevalence of the social science degrees, Group 1 concentrates 67%, and is headed

by Brazil (27%) and followed by Mexico (15.5%), Argentina (13.3%), and Colombia (11.1%). The second group is headed by Chile (9.8%), followed by Peru (5.4%), Venezuela (3.8%), and Ecuador (3.2%). The median values (2.5%) are represented by Panama and Uruguay. The lowest group (1.2%) is represented in the following order: Dominican Republic, Nicaragua, Bolivia, Costa Rica, El Salvador, Paraguay, and Honduras.

Another important thing to look at is the importance of evaluation and accreditation of degrees and courses in higher education. The total number of degrees and courses of all levels in higher education – master's degrees, doctorates, and specializations – amount to 5691, representing 17% of all courses developed in Latin America.

The following table shows Brazil's concentration of evaluated courses and degrees (50%). CONACYT Mexico has played a significant role in the strengthening of the national evaluation system, including the National Register of Researchers. The National Register of Postgraduate Programs (PNP) has two categories: International Level and High Level.

Argentina's effort is especially visible in the evaluation of doctorate courses. Uruguay has recently incorporated evaluation of courses and degrees, performed by ARCO SUR.

Brazil, with 1405 evaluated higher education courses, together with Argentina's 842 courses, represents 80% of evaluated doctorate courses in the region.

During the last decades, the Sistema Centroamericano de Evaluación y Acreditación de Educación Superior (SICEVAES) has made a systematic effort to ameliorate all aspects of university performance in Central America. Different guides for self-evaluation and external evaluation are recommended for the countries involved.

The following table shows the percentage of students in the social sciences in comparison with other disciplines (UNIVERSIA, 2013).

Country	*All degrees and courses*	*All social sciences degrees*	*All degrees w/evaluation*	*All higher education degrees w/evaluation*	*All degrees social sciences w/evaluation*	*All social sciences higher education careers w/evaluation*
Brazil	9205	3086	2890	1405	669	244
Argentina	4725	1534	920	842	313	312
Chile	3340	891	636	253	110	54
Mexico	5070	1749	636	0	227	0
Colombia	3480	1261	569	340	159	109
Uruguay	707	254	10	2	0	2
Perú	1829	643	2	0	0	0
Bolivia	572	172	0	0	0	0
Costa Rica	757	222	0	0	0	0
Ecuador	865	365	0	0	0	0
El Salvador	415	139	0	0	0	0
Honduras	258	81	0	0	0	0
Nicaragua	462	194	0	0	0	0
Panamá	819	287	0	0	0	0
Paraguay	350	121	0	0	0	0
Dominican Republic	587	213	0	0	0	0
Venezuela	1498	439	0	0	0	0
Total	34939	11322	5608	2842	1472	715

New Technologies: E-courses and Social Sciences

As an indicator of the new Technology and Innovation Centers (TICS) introduced in universities, the number of online courses offered has been quantified by country, for all disciplines and for the specific participation of the social sciences.

The region has 1679 degrees and courses online, representing 4.6% of all courses offered. Brazil leads the trend with 528 courses (31.48%), Colombia (16.6%), Mexico (14.8%), Argentina (13.4%), and Chile (6.1%)

The following table has grouped the countries by quartiles.

PAÍS	*All degrees/ distance learning & online*	*Social sciences/ distance learning & online*	*% in region's total*	*% of social sciences*
Brazil	528	256	35%	48.5%
Colombia	279	105	14%	37.6%

Continued

PAÍS	*All degrees/ distance learning & online*	*Social sciences/ distance learning & online*	*% in region's total*	*% of social sciences*
Mexico	249	135	19%	54.2%
Argentina	225	98	13%	43.6%
Chile	103	13	2%	12.6%
Peru	79	46	6%	58.2%
Ecuador	51	6	1%	11.8%
Nicaragua	35	25	3%	71.4%
Venezuela	33	11	2%	33.3%
Uruguay	23	18	2%	78.3%
Paraguay	12	6	1%	50%
Bolivia	5	1	0%	20%
El Salvador	4	2	0%	50%
Panamá	3	2	0%	66.7%
Dominican Republic	2	2	0%	100%
Costa Rica	0	0	0%	0%
Honduras	0	0	0%	0%
Total	1631	726	100%	44.5%

From this general analysis we can draw the conclusion that the development of the institutions of social sciences in the region has not been homogeneous. The influence of political ideologies and context has been, and still is, very strong. There is a general trend to focus on evaluation and excellence of degrees and postdoctoral studies, highlighting Brazil's leadership. The diversification of degrees and courses in the social sciences shows an adjustment to the global trend. Overall, the prevalence of social sciences is 40%. The National Councils of Science and Technology represent a new focus on excellence and competitiveness, and the formulation of scientific policies.

Social Science Infrastructure: East Asia and the Pacific (Research and Teaching)

Takashi Inoguchi, University of Niigata Prefecture, Niigata, Japan; and University of Tokyo, Tokyo, Japan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article traces the development of research and teaching infrastructure in social and behavioral sciences in East Asia and the Pacific. The first initiative in social science were made in Japan's before World War II. While bureaucratic authoritarianism and pervasive influence of Marxism impeded the development of research and teaching infrastructure in social and behavioral sciences, democratization under US-occupied Japan accelerated it. Second, infrastructure development in East Asia and the Pacific since 1945 is outlined. While foundations of opinion polling and survey taking were laid during colonial and authoritarian regimes, democratization and globalization have fostered and advanced social sciences in the academic world in East Asia and Pacific. Pan-Asian cooperation in social sciences is on the rise and research infrastructure is being developed that will facilitate cooperation and improving research infrastructures in the future.

Phases of Development in Japan after 1945

Modern social science originated outside Asia (Inoguchi, 1995). In Japan, modern social science initially meant, European-born Marxism planted onto Asian soil. Hence, the term social sciences described the 'opposition' science. *Oppositionswisssenschaft* meant the social theories of those opposing the regime. Opposition scientists wanted to reveal the oppressive and exploitative nature of the system. Marxist influence deeply permeated the international social sciences. Coupled with the overtly nationalistic undertones characteristic of Asia, Marxism hindered the diffusion of American behavioral and social sciences in the 1950s and 1960s. In other words, the dominance of Marxism in the social sciences in Asia posed higher barriers for American-style behavioral and social sciences, even in the 1950s and 1960s.

Furthermore, the dominance of state science, *Staatslehre*, the science that purported to be useful to the state's governance, had a lingering influence on the fledgling Japanese social sciences in the first half of the twentieth century and beyond. Instead of trying to come up with lawlike generalizations, state science was interested in supplying specific, concrete, and context-based knowledge. It encouraged historical and institutional descriptions. State science was interested in applied subjects like law and economics but not political science, sociology, or social psychology. State science was interested in history and geography, as far as they could be utilized in running the country and the colonies. Therefore, American social sciences were at first rejected because they were in stark contrast to opposition and state sciences.

Nevertheless, American-style social sciences started to permeate the rest of the world after 1945. The remarkable development of the American model of the professional academic market after the Second World War prepared the United States to excel in the social sciences in the latter half of the century. As carefully portrayed by Zunz (1998), the American model is based on a certain set of criteria within the academic community, characterized by competition and the loosely orchestrated concentration of government, industry, and the mass media to nurture and utilize academic resources and products. Furthermore, the influx of many European refugees stimulated American academics. The number of Nobel Prize winners from the United States was modest between 1901 and 1937, somewhat comparable to the figure of Japan after 1945. After 1938, however, the number of US Nobel Prize winners rose dramatically, achieving a dominant share.

Three major features of American-style behavioral and social sciences are: (1) a strong drive to come up with lawlike generalization; (2) a strong commitment to systematic empirical hypothesis testing; and (3) shared beliefs in anonymous referees producing good judgments and improved manuscripts. These features were not necessarily in harmony with the prevailing academic cultures of Japan in the 1940s and 1950s. Their interests lay in more historical and contextual descriptions, not necessarily in lawlike generalizations. Efforts to advance arguments were not necessarily made but by using systematic empirical hypothesis testing. Japanese scholars were extremely opposed to the idea of their work being anonymously refereed for publications. Thus, in the 1940s and 1950s, American-style behavioral and social sciences were not able to gain a foothold in Japan. Nevertheless, in the 1960s and 1970s, behavioral and social sciences as understood and practiced in the United States were slowly being adopted. This was also a period of extraordinary economic growth for Japan. In tandem with economic development, the academic infrastructure was consolidated, and academic orientations came of age in their national environments.

Institutional Structures of Social Sciences in Japan

The higher educational legacy of imperial Japan, which ended in 1945, contributed most directly to the shape of the academic infrastructure of the behavioral and social sciences in Japan after 1945. Its major features were:

1. an elitist structure of imperial universities with highly limited numbers of professors and enrolled students;
2. a curriculum serving the needs of the government in terms of supplying the elite cadres in applied areas of study such as medicine, agriculture, engineering, law, and economics; and

3. teaching two European languages, German and French, as well as English.

After 1945, the number of colleges and universities grew rapidly in US-occupied Japan, where each of the 47 prefectures built national universities. Furthermore, private universities grew in number in the 1960s and 1970s. The elitist nature of Japanese universities decreased considerably throughout these years. Rather, Japan registered a high admission rate of high-school graduates comparable to that of the United States, thanks to a very inclusive enrollment scheme. Curricula also changed together with the extraordinary growth of student enrollments and staff appointments from the 1960s to the 1990s. In the case of the University of Tokyo, for instance, the relative proportion of staff appointments remained the same. There have been more staff appointments in applied science areas, especially engineering, the life sciences, medicine, pharmacology, and agriculture. As of 2000, 80% of the annual budget allocation goes to those applied science areas. Only 20% goes to law, economics, literature, education, and other nonscience areas of study. The tendency of favoring applied sciences budgetwise further increased in the twenty-first century. There also seems to be an according increase in Nobel Prize winners from Japan. However, at most private universities, applied sciences have not been well prioritized in terms of faculty development and student enrollment, thanks to the general scarcity of funding as a whole.

However, this does not mean that a favorable national environment has been created for the development of the behavioral and social sciences. Within the schools of law, economics, and literature, behavioral and social sciences have not been given autonomous statuses in terms of staff appointment and budgetary allocation. The political science discipline has been included into the discipline of law (a legacy of state science); the school of economics has a curriculum giving very high importance to applied economics and history; and the school of literature has departments of sociology, social psychology, and anthropology. Moreover, the emphasis on European languages was replaced by the predominant use of English after 1945. This has facilitated the diffusion of American-style behavioral and social sciences.

Financial Setups of Behavioral and Social Sciences

The Funding of Social Science Research

Turning to the topic of institutional and financial setups, there are three major ways in which behavioral and social science research is conducted:

1. within the university system;
2. by nonuniversity institutes; and
3. project funding through national organizations and foundations.

Behavioral and social science research is predominantly conducted within the university system. Small-scale research is normally conducted by making best use of a small amount of research budget made available to each professor. At some universities, schemes for facilitating larger and more interdisciplinary research exist. However, the size of budgets tends to be small. Therefore, once research has higher funding needs, researchers can apply for more budgets through other schemes.

In addition to the university system, there are some research institutes primarily devoted to the planning, implementation, and dissemination of research on national and sometimes international spheres. They used to be entirely publicly funded but are now financed by a mix of private and public funding. For example, the National Museum for Ethnographic Research in Osaka focuses on anthropology. Thus, the institute organizes various projects with professors working at different universities. The Institute of Statistics and Mathematics in Tokyo is a similar organization that focuses on public opinion research. Some institutes work on public policy-related research topics like 'public policy priorities in aging societies', whereas others work on more purely academic subjects like 'life style, post-modern, post-Confucian, and post-Marxist'.

The system of project funding through national organizations and foundations is important in Japan. In Japan, the Japanese Society for the Promotion of Sciences plays a similar role to that of the National Science Foundation of the USA, giving financial support to various academic projects (the Japan Society for the Promotion of Sciences 2000). The National Institute for Research Advancement in Tokyo is an organization that funds mainly public policy-focused projects run by various think tanks in Japan and elsewhere. The Japan Foundation in Tokyo is a foundation financed by public funding to assist research financially and to disseminate academic, artistic, linguistic, and other professional projects globally. Many private foundations exist in Japan and South Korea in addition to those public organizations and foundations. Some focus on gender studies, academic and professional exchanges, human security, and international financial needs, whereas others give to more public policy-related projects. In Korea, the Sejong Institute is public and privately funded and works on a variety subjects in sociology, political science, and urban studies.

Financial Setups of Research Infrastructure Development

In terms of infrastructure development for the behavioral and social sciences, the university system is central and important. Most project-focused funding does not include infrastructure development. Support for developing academic infrastructures, such as joint centers for survey research, experimental laboratories, interuniversity consortiums for databases, electronic networks, or publishing houses, usually comes from public funding.

A joint university center for survey research does not exist in Japan. What exists is a 3- to 5-year partnership based on the project funding of scientific research. Within this coalition, researchers can assemble a research team and hire an opinion polling company for surveys. When the project ends, everything except the database and published volumes disappears. My own scientific research project is a recent example of this. It was funded by the Ministry of Education for over 4 years (1999–2002) and deals with 'Globalization and the Cultural Dimensions of Democracy in 18 Societies of Asia and Europe'. It has 1000 data points in each sample, collected by face-to-face interviewing (Blondel and Inoguchi, 2006; Inoguchi and Blondel, 2009; Inoguchi and Marsh, 2009). A number of universities such as the University of Tokyo and Keio University

in Tokyo have departments of social psychology and sociology, and research centers/institutes for research by mass communication. However, none of them encourage partnership/team building or undertake coordinating roles institutionally.

The same happens with experimental laboratories. Again, they must be built within project funding for scientific research and can be maintained and expanded if they continue for several years. One recent example is Toshio Yamagishi's experimental laboratory built to examine experimental and cross-national modes of trust (Yamagishi, 2000). With regard to social scientific databases, the University of Tokyo's Institute of Social Sciences has set up an interuniversity consortium for databases in a similar fashion as the University of Michigan's Interuniversity Consortium for Social and Political Research. Focusing on sociological, political, historical, and economic Japanese data, the consortium has been quite a success, albeit on a rather small scale, in organizing available databases and making them academically totally open and accessible to its members.

Election networks are funded by the Japanese Society of Promotion of Sciences and the Ministry of Education. With their funding, Ikuo Kabashima has conducted seven Japanese election panel surveys through the 1990s, producing six published volumes dealing with various aspects of Japanese electoral behavior (Kabashima, 1998–2000). Kabashima's database has largely expanded the database of the Journal called *Leviathan: The Japanese Journal of Political Science*. The database has been more narrowly focused on election data and has run on a much smaller scale.

Publishing houses dealing with behavioral and social science books do not necessarily thrive. Given the fact that orders by major university, libraries are irregular, academic publishers cannot anticipate amount of books that will be purchased. In this sense, the infrastructure for publishing research needs to be further consolidated. There is no meaningful contribution of English-language research to research publications. Kodansha International is the only commercially self-sustainable publisher in the English language. However, this publisher is not primarily focused on academic books. The United Nations University Press in Tokyo was quite successful in the late 1990s in continuously publishing good academic books on such topics as democracy, humanitarian interventions, and the global environment, albeit on a modest scale. Their publications have been distributed in North America by the Brookings Institution Press and have also been included in the Columbia International Affairs Online (CIAO) Internet service on new publications. University presses such as the University of Tokyo Press and Kyoto University Press have English-language publishing departments. However, they only publish sporadically and their published books are mostly based on translations of books originally written in Japanese.

Research and Teaching Infrastructure in Social and Behavioral Sciences in East Asia and the Pacific in the Twentieth and Twenty-First Centuries

The Foundations of Social Science under Colonial Rule

The development of research and teaching infrastructure in social and behavioral sciences in East Asia and the Pacific is related both to the governance under colonialism and after independence or in other words to authoritarianism and to democratization. The first steps toward setting up a research infrastructure were made under colonialism and post-independence authoritarian regimes. These regimes were interested to find out preferences and issues of citizens living under colonial or postindependence rule. For instance, in 1937, opinion polling was carried out for the first time in British Malaya because colonial authorities wanted to understand better what people perceived and preferred with regard to the kind of news items through Singapore Radio Station. However, opinion polling was only carried out sporadically under colonial rule. As Sen notes (1983), British India's colonial authorities were indifferent to poverty and famine, whereas the postindependent Indian government has been far more attentive to poverty with the result that the incidences of large-scale famine dramatically decreased. Sen credits Indian statisticians in developing infrastructure in gauging poverty and implementing rescue operations. Postindependence authoritarian governments did make use of opinion polling, but it was limited because for reasons of internal security and of constraints on freedom of expression, opinion polling never blossomed. Under authoritarianism questions tended to elicit progovernment voices unduly, whereas respondents tended to voluntarily suppress what might be taken as disturbing authoritarian governments.

The Fostering of Social Science Practice with Democratization

A more fully fledged development of research infrastructure came in tandem with democratization. It was in the 1980s during which opinion polling and other research and teaching infrastructure started to blossom. The advent of democratization in East and Southeast Asia meant that politics had to pay more attention to what and how people felt thought and decided on issues related to politics (Marsh et al., 1999; Blondel and Inoguchi, 2006; Inoguchi and Blondel, 2009; Inoguchi and Marsh, 2009; Chu and Wong, 2010).

In 1986, anti-Marcos people power party in the Philippines put an end to dictatorship. Consequently, opinion polling became more important. The Social Weather Stations (SWS) was founded in 1986 in order to regularly poll the people's opinions without government funding. In a similar vein, in Taiwan, opinion polling became a routine after Jiang Jinguo initiated the path toward democratization (Yu, 2012). In South Korea, democratization began under Roh Tae Woo, who was first democratically elected president. A democratic regime was consolidated under Kim Dae Jung who was the second democratically elected nonmilitary president from 1998 to 2003 and after (Cho, 2012). In Thailand, a constitutional revision took place in 1992, which paved the way toward democratization. Under Thaksin Shinawatra and his successor Ingluck Sinawatra, opinion polling became a common practice. Authoritarian regimes in Malaysia felt the need to loosen regulations by asking academics at the Universiti Kebansan Malaysia to carry out an opinion poll on voters and voter intentions 'like it was being done in the United States' in 1986 (Idid, 2012).

The Influence of Globalization on Research Infrastructures

Another important impetus in the 1990s and early 2000s was the steady tide of globalization. New advances in communication technology were driving forces that made the world 'flat', enabling a vast number of people all over the world to communicate and connect to each other with incredibly fast speed, at low costs and give access to massive content (Friedman, 2000). This had two effects on the infrastructure of social sciences. On the one hand, globalization enabled a massive number of people to participate in politics. Especially, the Internet and social media has supported people and interest groups in connecting to each other. These groups are often larger than the small governing elites. Globalization in this sense is contributing to democratization. About 300–500 million users are engaged in Chinese Social media, which emphasizes the possibility for China's vast population to connect and exchange thoughts and feelings (McDougal, 2011). Positively, people's voices are far more widely expressed, thanks to the ease of communication technology. To gauge the vox populi, opinion polling has advanced by leaps and bounds. On the other hand, the prompt and often massive responses to the regime's action or nonaction often results in the regime's sources of procrastination, wavering, or even termination to the initial action or nonaction itself.

Strengthening the Asian Research Base

Social science research in Asia in general and particularly in Japan and Korea has become well institutionalized in its respective national settings and organizational structures in the second half of the twentieth century. The two strong legacies of state science and opposition science that were prevalent in the first half of the twentieth century have weakened in Japan and Korea. Nevertheless, they provided a fairly solid foundation for social science research in the second half of that century (for such developments in political sciences in Japan, South Korea, and China, see Inoguchi, 2012a). Although its infrastructure needs to be improved in the future, the stage is clearly set for further consolidation of social sciences, especially in light of the two pronounced trends of international cooperation and cross-national comparisons.

In Japan and Korea, as well as in Asia in general, international cooperation began with the increasing collaboration with the United States. The United States have been a senior partner for the larger part of Asia's recent history. Through bilateral research and teaching with the United States, both Japan and Korea enhanced their national bases of social science research by the end of the twentieth century. By then, it had become obvious that international cooperation had become a trend in the United States, as well as in Asia. In much of the latter half of the twentieth century, regional cooperation did not flourish much partly because of diverging economics and politics. However, during the 1990s, Asian-Pacific countries, specifically Japan, Korea, China, and the 10 Association of Southeast Asian Nations members, came to interact among themselves.

It is not surprising that the new trend of enhanced intraregional research cooperation is in broad harmony with the increase in intraregional summit meetings. It may seem as if the newly found regional (i.e., Asian) identity supported this trend. However, the increase in intraregional research cooperation was primarily because of a growing interest in cross-national comparisons. After recording national achievements in terms of per capita income and literacy levels, it has become a norm to compare cross-national propositions. This has replaced the traditional approach of focusing on national patterns and developments. Nevertheless, there is still a long way to go until we can speak of an overall Asian social science. Yet, a number of such seeds have already been sown and the prospects are not bad. Globalization has changed the state–society relationship tremendously. An Asia–Europe survey comprising nine societies from Asia and nine societies from Europe was carried out in 2000 under the leadership of Takashi Inoguchi and Jean Blondel (Blondel and Inoguchi, 2006; Inoguchi and Blondel, 2009; Inoguchi and Marsh, 2009). The survey aimed to examine how citizens relate to the state by focusing on three variables: identity, trust, and satisfaction. This project represented a new method of establishing and enhancing intraregional and interregional cooperation. Academics in both regions benefit from working together: Asians learn from each other and build infrastructure for cooperation. Europeans discover more similarities than differences between Europe and Asia.

Another survey that was carried out was the General Social Survey in Japan, Taiwan, South Korea, and China, which used national resources to coordinate a questionnaire in order to conduct cross-national comparisons (Iwai et al., 2011). Its impetus was the global diffusion of US-led general social survey in East Asia.

Up until the late 1990s, the leadership for social science research cooperation in Asia–Pacific came primarily from the United States. Since then, there have been many local initiatives for intraregional cooperation, originating in Korea, Japan, Singapore, and Australia. As there has not been an all-inclusive regional social science research council taking conceptual leadership and funding facilitation, like the United States Social Science Research Council has long done, there are no definite outcomes at this point. Nevertheless, there are many budding initiatives and publications on subjects, such as national identity, globalization, democratization, human rights, and civil society. Universities such as the University of Tokyo, the University of Hong Kong, Yonsei University, Academia Sinca, Chularonkorn University, the National University of Singapore, and the University of Malaya as well as think tanks like the Institute of Southeast Asian Studies (Singapore), the Japanese Center for International Exchange (Tokyo), and the United Nations University (Tokyo) are major agents for more academic research. With the resulting, cumulatively enhanced networks within Asia–Pacific, one can hope with some cautious optimism that there is a development of pan-national social science in the region. Interregional social sciences would surely synthesize a diversity of views and angles that would add to empirically testable comparisons on major trends and patterns of democratization, digitalization, and globalization and their differentiated impacts on local societies.

Asian Barometers and Other Types of Scientific Research

After the first edition of The International Encyclopedia of Social and Behavioral Sciences was published in 2001, a tidal wave of development took place in terms of infrastructure buildup in East Asia and the Pacific. The American Political Science Section of Comparative Democratization's Newsletter published a special issue on regional barometers in which the leaders of key regional barometers summarized their aims, scopes, and findings. Along with the Afro barometer, the Arab barometer, the Latinobarometer, the Americas barometer representing each world region, the AsiaBarometer (Inoguchi, 2012b) and the Asian barometer are allotted barometers, representing Asia. The AsiaBarometer focuses on the quality of life (Shin and Inoguchi, 2009; Inoguchi and Fujii, 2012; Inoguchi, 2013), whereas the Asian barometer focuses on democratization (Dalton et al., 2008; Chu et al., 2010). The former has been carried out seven times, in almost every year of the 2000s (2003, 2004, 2005, 2006, 2007, 2008, and 2010), covering the entire Asian continent (East, Southeast, South, and Central). The Asian barometer has been carried out three times since 2002, mostly in East and Southeast Asia. The former is led by Takashi Inoguchi and his pan-Asian team, whereas the latter is led by Yun-han Chu and his hybrid team of East Asian and American academics. In this regard, the AsiaBarometer is distinguished from all the rest in that the rest are led by the combined American and regional leaders or they follow more or less standardized schemes of democratization adapted to each region even when leaders are from each region.

Besides opinion polling, other kinds of behavioral and social scientific research have blossomed recently. Social psychological experimental research has advanced especially in the fields of trust and cooperation (Yamagishi, 2000). Using prisoner's dilemma examples in game theory, Yamagishi and his team reveal cross-national similarities and differences among Japanese, American, and Chinese subjects. It highlights that Americans and Chinese are more proactive in taking cooperative initiatives, whereas the cautious Japanese tend to decline cooperative initiatives at first. Neurological behavioral research has flourished more recently focusing on neuroeconomic and neuropolitical behavior with regards to values and group formation, justice, and utilitarian calculus (Takahashi, 2011; Kato and Okada, 2011). It also highlights the incongruence between neurological response and verbal response in judging happiness, efficiency, and rights. Computer simulation is another area, registering behavioral research advances. On the basis of almost verbatim decisions of leaders leading to the Cuban missile crisis, Yamakage and his team have advanced the use of computer simulation one step forward. More system-founded computer simulations are also being developed to show insight into hegemonic change (Yamakage, 2011). Competing models of world leadership transition are shown with contrasting results.

Besides regional barometers, other infrastructural development should be noted. The SWS of the Philippines has carried out democratization and all the related subjects in the Philippines since 1986. Its impetus is Philippine democratization in 1986. The Center for the Study of Developing Societies, New Delhi, has a section of opinion polling in India, in which Yogendra Yadav and his team have carried out democratization studies on a subcontinental scope (Stepan et al., 2011). Public Opinion Program of the University of Hong Kong led by Robert Chung has invented a scheme of polling on citizens' political preference and some economic indicators. Its impetus is the return of Hong Kong from Britain to China in 1997 (Lee, 2012).

Looking Forward

Into the second decade of the twenty-first century, the prospect for progress in research and teaching infrastructure in social and behavioral sciences in East Asia and the Pacific is bright. Not only Japan and Korea but also Taiwan, Hong Kong, Singapore, China, Macao, Thailand, the Philippines, Malaysia, and Indonesia have been consolidating their infrastructure and research products based on such new infrastructure quite steadily and increasingly in concert in the region. I highlight three new developments in this regard. First, the region-wide associations and networks are sprouting and flourishing. The Asian Network of Public Opinion Research (ANPOR) was established with close ties with the World Association of Public Opinion Research and the American Association of Public Opinion Research. The first annual meeting will be held in Seoul in November 2013 some 100 members assembled from East Asia and the Pacific. Its journal, the Asian Journal of Public Opinion Research, has started publication in digital format in November 2013. The Asian Consortium for Political Research (ACPR) has been reconfigurating and consolidating itself with a new journal provisionally called Asian Political Science Review to be launched in 2015.

Second, research cooperation across national borders has started to flourish. Quality of life and democracy are two of the favorite subjects on which research cooperation has yielded most. The AsiaBarometer survey directed by Takashi Inoguchi was able to cover the entire Asian region (29 countries and areas) with focus on quality of life. The (East) Asian barometer headed by Yun-han Chu with the Asian and American team was able to cover some of East Asian and Southeast Asian countries with focus on democratization. More recently, the ANPOR has conducted its cross-national survey with focus on daily life satisfaction in Japan, Korea, Thailand, China, India, Malaysia, the Philippines, Macao, Taiwan, Hong Kong, Myanmar, and Pakistan. The Center for Empirical Political Science Research at the University of Niigata Prefecture has started to conduct e-mail survey research with focus on diverging varieties of democracy (direct democracy, procedural democracy, communitarian democracy, monitory democracy, and cosmopolitan democracy) through cooperation of political scientists in three academic associations: i.e., the American Political Association, the European Consortium for Political Research, and the ACPR.

Third, new forms of interdisciplinary research are on the rise. Utilizing insights from neuroscientific findings, Ken Suzuki (2013) has proposed the concept of divicracy. The notion of individual is tightly embedded with the modern

theory of representative democracy. Neuroscience has made it crystal clear that one person is divisible, i.e., one person can have many ideas and preferences without insisting on consistency and integration. Suzuki's mathematical formulation of divicracy based on this neuroscientific insight is iconoclastic of modern Western thought. Here, we find an infusion of neuroscience, physical science, and ethics. In East Asia and the Pacific, teaching often takes interdisciplinary forms and those barriers, which used to stand between humanities and social sciences on one hand and natural and medical sciences on the other seem to be reduced substantially in many schools. Although future developments are not quite clear at this moment, I am confident that the future is bright in the development of research and teaching infrastructure in social and behavioral sciences in East Asia and the Pacific.

Abstract

East Asia and the Pacific are economically developed. Yet, we know very little about the research, knowledge generation, and broader interconnections of universities and colleges in this region. After becoming industrially developed, what kind of problems and issues is this region faced with academically? Who are the institutions that can inform governments, and offer policy recommendations? Are they different from other research institutions in the Western world? This article introduces 10 social science research academies from the US, Australia, China, Singapore, Taiwan, Hong Kong, Japan, and Korea in order to understand their role, functions, and characteristics.

Academic Excellence in East Asia and the Pacific

After more than three decades of economic growth from the 1970s to the 1990s, the East Asian and Pacific region have entered a new age of technological advancement and innovation through research and development (Kim and Nelson, 2000). Universities, academies, and businesses (those elements which propelled US technologically in the developmental change in the 1970s and the 1980s) are now redefining the East Asian and Pacific countries' technological development and economic growth (Jorgenson, 2001). As Harvey Brooks and Lucien Randazzese mention: "Starting in the 1970s, and increasingly in the 1980s and 1990s, federal and state governments in the United States have established programs to stimulate formal university-industry relationships" (1998: 361). Having witnessed the success of the US in linking universities with industries, East Asia (China in particular) has invested heavily in research institutions and universities so they can compete with world class universities (Ma, 2007: 31–53). On the social sciences front, research and development in democratization, industrialization, regionalism, poverty reduction, economic development, social changes, political development, etc., regional governments require enormous support, insights, and policy recommendations from research institutions, centers, or academies. This is why social science academies in East Asia and the Pacific deserve detailed attention.

In a BBC report in February 2013, Prof Alan Smithers from Buckingham University admitted that "there was a group of countries and territories that generally performed better than England in all tables [education and tests], including Hong Kong, Japan, Singapore and Taiwan" (BBC news http://www.bbc.co.uk/news/education-21296635 (accessed 05.02.13.)). He went on to say that UK educational institutions should try to learn from these countries or territories to be more competitive in the world. In the *Index of Cognitive Skills and Educational Attainment 2012* (a global comparison of education prepared by Pearson and the Economist Intelligence Unit), four of the top five countries were in East Asia, in addition to Finland which ranked first: South Korea (2nd), Hong Kong (3rd), Japan (4th), and Singapore (5th). Sir Michael Barber, Pearson's chief education adviser, attributed the success of these East Asian economies of having a 'culture' of education (Sean Coughlan, "UK education sixth in global ranking" http://www.bbc.co.uk/news/education-20498356 (accessed 05.02.13.)). On the global higher education comparison, the *Times Higher Education World University Ranking of 2012* indicated that five universities from East Asia ranked among the top 50, between 23rd and 50th (Times Higher Education World University Ranking http://www.timeshighereducation.co.uk/world-university-rankings/2013-14/world-ranking/region/asia (accessed 01.11.13.)). Turning to the *QS World University Rankings 2013*, the picture has become more obvious for the rise of East Asia in global higher education competition. Among the world's top 50 universities, there were 10 universities from East Asia, ranked from 24th to 48th (QS World University Rankings http://www.topuniversities.com/university-rankings/world-university-rankings/2013#sorting=rank+region=71+country=+faculty=+stars=false+search= (accessed 01.11.13.)).

Kishore Mahbubani, Dean of the Lee Kuan Yew School of Public Policy at the National University of Singapore, contended that the shift of the global power from the West to the East is 'irresistible' (2008). Hong Kong, Taiwan, Singapore, and China also witnessed the extraordinary investment in tertiary education and the expansion of many research institutes, postgraduate programs, and overall higher education expansion in the 1990s and 2000s, which resulted in a golden era of higher education development in East Asia.

In the following sections, we are going to introduce 10 research institutes or academies in East Asia and the Pacific region to focus on their function, role, characteristics, development, etc. We begin with two institutes in the Pacific – the East-West Center (EWC) in Hawaii, US, and the Academy of the Social Sciences in Australia (ASSA). These two academies represent two western countries' investment in policy research, academic exchanges and cultural development in East Asia and the Pacific. Then, we look at four academies in the Greater China region; the Chinese Academy of Social Sciences (CASS) in the People's Republic of China, the Academia Sinica in Taiwan, the Universities Service Centre for China Studies (USCCS), and the Hong Kong Institute of Asia–Pacific studies (HKIAPS), both at the Chinese University of Hong Kong. CASS, under the State Council, is the largest social sciences academy in China. The Academia Sinica is the highest and most prestigious academy in Taiwan, and includes physical and social sciences. The USCCS is a university level research institute with

a long history. Previously known as USC, it is a well-known institute focusing on contemporary Chinese studies. The HKIAPS has 23 years of history and increasingly performs an important role in linking Hong Kong between China and the Asian Pacific region with its high quality academic research and policy-oriented studies.

In addition, we will examine the East Asian Institute (EAI) and the Institute of Southeast Asian Studies (ISEAS), both at the National University of Singapore. EAI is a research institute focusing on China and its relations with the East Asian region; while the ISEAS is one of the largest research institutes in the world focusing on Southeast Asian studies. Finally, we look at the Institute of Social Science (ISS) of the University of Tokyo in Japan and the East Asia Institute (EAI) in South Korea. The ISS has more than 50 years of history in applying social sciences to serve Japan's economy and society. The EAI is a renowned think tank looking at the international relations of the East Asian region. The choice of the academies reflects the aforementioned transformation of East Asia from industrial and manufacturing workshops to knowledge centers. This list is by no means comprehensive. The selected institutions merely aim to cover some major academies which have had significant impact on academia and policy-making.

The East-West Center (EWC), Hawaii (US)

The EWC was established by the US Congress in 1960 in order to promote "better relations and understanding among the people and nations of the United States, Asia, and the Pacific through cooperative study, research, and dialogue" (http://www.eastwestcenter.org/about-ewc/mission-and-organization (accessed 10.11.13.)). Its 21-acre Honolulu campus, designed by the famous Chinese architect, I.M. Pei, is next to the University of Hawaii, Manoa. The choice of Hawaii was unique in the sense that the geographical location is at a meeting point between the Asian Pacific region and the United States mainland. Established during the height of the Cold War, the EWC today provides many academic courses and offers a forum for free-thinking among the students, fellows, and visitors. In its 50 years history, it has already produced more than 57 000 alumni, and has more than 750 partner organizations.

The EWC is governed by an academic board of 18 members and currently chaired by Dr Charles Morrison. Its cultural, academic, research, and exchange missions are supported by nine related programs and bodies: the EWC Research Program, the EWC Education Program, the EWC Seminars Program, the EWC Pacific Islands Development Program, the EWC in Washington, the East-West Center, Office of External Affairs, the EWC Foundation, and the Office of Administration.

Through these nine fellowship programs, students, researchers, scholars, and academics can fully be engaged with the EWC. Apart from these fellowships, students can apply for the Asia Pacific Leadership Program Fellowship (the flagship program which has run for 13 years), the Asian Development Bank-Japan Scholarship Program (a link-up program with the University of Hawaii, Manoa), the East-West Center Graduate Degree Fellowship (a 24-month program supporting Master or PhD students), the Jefferson Fellowships Program (a 3-week short program), the Obuchi Student Scholarship, the Pohang Iron and Steel Company (POSCO) Visiting Fellowship Program (2-month program in relation to Korean studies), the ProSPER.Net Leadership Program (jointly developed with the United Nations University Institute of Advanced Studies [UNU-IAS]), and the United States–Timor-Leste (USTL) Scholarship (a newly developed program).

With the expert knowledge and specialization of fellows, visitors, and students, the EWC focuses on three major research areas, the Environment, Population, and Health; Innovation, Energy and Economic Growth; and Governance, Security and Justice. Research results, policy recommendations and reports, etc. are disseminated through seminars, conferences, and workshops, as well as through publications such as the *Asia Pacific Bulletin*, *AsiaPacific*, and other policy briefs and recommendations. Finally, the EWC in Washington allows more engagement and networking between policy makers and academic scholars through outreach activities, seminars, and publications.

Academy of the Social Sciences in Australia (ASSA)

As one of the oldest academies in Australia, the main objective of the ASSA is "… to advance the development of world-class social sciences in Australia and their contribution to local, national and global well-being" (http://www.assa.edu.au/about/plan (accessed 12.11.13.)). The ASSA was established on 7 July 1971 with 94 members on the Social Science Research Council of Australia as foundation fellows. In connection with the Australian Academy of the Humanities (AAH), Australian Academy of Science (AAS), and the Australian Academy of the Technological Sciences and Engineering (ATSE), these four academies provide interdisciplinary advice to the Australian government through the Australian Council of Learned Academies (ACOLA). According to the Strategic Intentions 2013–15, ASSA aims to achieve four missions:

- Promoting research, teaching, and advice in the social sciences
- Promoting national and international scholarly cooperation across disciplines and sectors, including collaboration with other academies
- Commenting on national needs and priorities in the social sciences
- Providing advice, especially on issues of national importance (http://www.assa.edu.au/about/plan (accessed 16.11.13.))

To facilitate these missions, the ASSA has developed five programs: An Annual Symposium, Public Lectures, Roundtables, State-based Fellows' Initiatives, and the Workshop Program. The Annual Symposium, the flagship program of the ASSA, is organized in November in Canberra. This one-day workshop, together with the concomitant Cunningham Lecture, addresses key issues in Social Sciences. Public Lectures, sponsored by the ASSA, are hosted by individual universities in order to help the outreach of ASSA. Academy Roundtables are forums to provide policy input and practical perspectives through interaction with high-ranking

government officials, leading academics and academic fellows. The State-based Fellow's Initiatives funds and helps fellows to organize their own workshops to deal with local issues. The Workshop Program performs a key function of the ASSA which is to tap into cutting edge knowledge in Social Sciences, especially in applying technology in lifting the productivity of Australia.

Currently, three funding and award schemes of ASSA are the major vehicles to promote academic excellence and global outreach. The International Program provides funding for established or young academics in Australia to travel overseas and build academic partnerships with other leading academics in the world. The Paul Bourke Award for Early Career Research (formerly Academy Early Career Award) is an annual award for outstanding academic work in Australia, chosen from four nominees in their respective social sciences categories. The Workshop Program grants academics for the organization of a 2-day workshop to promote the discussion of topical social science issues with policy significance. It generally funds six academic workshops annually. The dissemination of ASSA's research is done mainly through dialogs, papers, research publications, symposium publications, and workshop publications.

The Chinese Academy of Social Sciences (CASS)

The Chinese Academy of Social Sciences (CASS), previously the Department of Philosophy and Social Sciences under the Chinese government was established in 1977. It was almost completely destroyed during the Cultural Revolution (1966–76). The first president of the academy was Qiaomu Hu (1977–82). The current President is Weiguang Wang. It is the highest research organization under the State Council of the People's Republic of China. Included in it are more than 31 research institutes and 50 research centers, covering 260 research areas, such as law, economics, political science, sociology, geography, demography, linguistics, American studies, Japanese studies, European studies, Asian Pacific studies, Eastern European studies, Russian and Central Asian studies, African studies, Latin America studies, world economics and politics, and others. In total, CASS employs more than 3767 staffs, of which 2975 are researchers (http://bic.cass.cn/english/InfoShow/Arcitle_Show_Cass.asp?BigClassID=1&Title=CASS (accessed 23.11.13.)).

CASS aims to promote theoretical as well as policy-oriented research on various disciplines of the social sciences. Among the various research activities are a program for visiting scholars, joint research collaboration, training programs, seminars, workshops, and public lectures. It has built up research connections with more than 200 global research institutions. While, CASS is serving a research purpose, the administrative arm of CASS is the Bureau of International Cooperation (BIC), which takes care of all the administrative works, including liaising and setting up agreements with foreign institutions, facilitating scholars and researchers in getting visas and passports for overseas research, and facilitating foreign scholars coming to China to carry out researches, etc. In the publication *2012 Think Tanks and Civil Societies Program*, CASS ranked 5th out of the 100 non-US think tanks and 1st among the 45 think tanks in the Northeast Asian region (2013: 42 and 57).

Academia Sinica, Taiwan

Academia Sinica was established in 1928 in the Republic of China (ROC) as the most prestigious academic institute researching physical and social sciences. After the ROC was moved from China to Taiwan in 1949, Academia Sinica gradually reestablished itself in Taipei. Particularly its former President, Yuan-Tseh Lee, (Nobel Prize winner in Chemistry 1986) made great strides in advancing Academia Sinica. There are now 24 research institutes and seven research centers covering three broad areas included in Academia Sinica: mathematics and physical sciences; life sciences; and humanities and social sciences (http://home.sinica.edu.tw/en/about/history_and_mission.html (accessed 24.11.13.)).

The highest academic institute of the ROC, Academia Sinica is directed by the Council of Academia Sinica, its President, and the Convocation. The Convocation is made up of 261 Academics, of whom 111 are active in Mathematics and Physical Sciences, 88 in Life Sciences, and 62 in Humanities and Social Sciences. The Convocation performs four functions:

- To elect academicians and honorary academicians
- To elect members to the Council of Academia Sinica
- To design policies on academic research
- To plan and carry out research at the government's request (https://db1n.sinica.edu.tw/textdb/academicians/index.php?lang=en (accessed 24.11.13.))

According to Chi Huey Wong, the current President, "… the foremost academic research institution in Taiwan, Academia Sinica has the mission to promote cutting-edge research in the humanities and sciences, cultivate academic talent and issue policy advisories to the government" (http://home.sinica.edu.tw/en/about/message.html (accessed 24.11.13.)).

Within Humanities and Social Sciences, the Academia Sinica has 12 research institutes. They are the (1) Institute of History and Philosophy, (2) the Institute of Ethnology, (3) the Institute of Modern History, (4) the Institute of Economics, (5) the Institute of European and American Studies, (6) the Institute of Chinese Literature and Philosophy, (7) the Institute of Taiwan History, (8) the Institute of Sociology, (9) Institute of Linguistics, (10) the Institute of Political Science, (11) the Institutum Iurisprudentiae (Institute of Law), and (12) the Research Center for Humanities and Social Sciences. Although they are under the umbrella of the Academia Sinica, each institute has its own administrative and research staff, and its own library and conference facilities. In fact, in order to qualify as an institute under the Academia Sinica, the institute has to go through a 10-year probation period, in which numerous assessments are used to evaluate its research strength and capacity.

Apart from research, the Academia Sinica actively promotes higher education, international academic exchange programs, organizing lecture series, providing international faculty services, etc. These and many other activities are facilitated by the International Affairs Office. The Academia Sinica also offers

degree programs and higher degree programs. Its PhD degree program, established in 2006, is facilitated through its Taiwan International Graduate Program (TIGP) and the partnership with other leading universities in Taiwan.

The Universities Service Centre for China Studies (USCCS)

Among senior scholars and academic workers involved in contemporary Chinese studies of the People's Republic of China (PRC), the importance of the University Services Centre (USC) is well-known. Its nickname, the 'Mecca for China Studies,' speaks for itself. Acquiring academic footage in the PRC during the Cold War and in particular during Mao's era was highly difficult, if not totally impossible. One of the key difficulties facing Western (even Chinese) scholars was the location of original sources, materials, and archives of the PRC. The idea of developing a center on contemporary Chinese studies was first conceived by Lucian Pye, professor at Massachusetts Institute of Technology (MIT), and Bill Marvel, president of Education and World Affairs in the US during the 1950s. (Another two centers on China studies were at the University of Washington and Harvard University.) They were thinking of setting up a center in Hong Kong, as a gateway between China and the West. The Social Science Research Committee and the American Council of Learned Societies helped the setting up of a scholars' committee which was funded by Carnegie–Mellon and the Ford Foundations (Vogel, 2005: 2–3).

The center was first established in an old building in 155 Argyle Street in Kowloon, Hong Kong. Its first director was Jerome Cohen. It moved to the Chinese University of Hong Kong in 1988 and was later renamed the Universities Service Centre for China Studies (USCCS). According to Ezra Vogel (Emeritus professor from Harvard University), "…several of the academics who conducted research at the Centre became themselves distinguished government servants: Stephen Fitzgerald became the first Australian ambassador to China, Richard Solomon became an assistant to Henry Kissinger in the early stages of the US–China relationship, Michael Oksenberg was central to normalizing relations between the United States and China, and David Wilson, the last civil servant to be governor of British Hong Kong, played a key role in negotiating China's resumption of sovereignty over the territory" (Vogel, 2005: 1).

USCCS helped nurture many academics with its abundant resources during the time when China was still closed to the outer world and research materials of the PRC were scarce. In terms of its research and archive, it owns more than 250 provincial and national newspapers from mainland China and over 1500 periodicals (Chinese mainly) from as early as the 1950s. As a center for Chinese studies, it houses one of the most comprehensive lists (over 1300) of Chinese regional and statistical yearbooks. It has its own library with more than 80 000 Chinese and English books on contemporary Greater China and the East Asian region. It is also equipped with online materials, electronic resources, microfilms, and other digitized scholarly papers on contemporary China, in both English and Chinese (http://www.usc.cuhk.edu.hk/Eng/Default.aspx (accessed 29.11.13.)). In terms of research dissemination, a weekly luncheon seminar where visiting scholars, researchers, and students all mingle to share research findings has long been a tradition of the USC, Some of the results will be published within the USC Seminar Series. Starting from 2005, the USC began to launch the Graduate Seminar on China, an annual event to promote Chinese studies across Asia and the world.

The Hong Kong Institute of Asia–Pacific Studies (HKIASP)

HKIAPS was established in 1990 as a result of its former Vice-Chancellor Professor Charles Kao's (Nobel Prize winner in Physics 2009) initiative to develop an institute of social studies supporting research on Hong Kong, China, and the Asian Pacific region. It is managed by a committee of 11 people. In its 20th Anniversary publication *HKIAPS at 20*, it laid out its mission to "promote multidisciplinary research on social, political, and economic development of Hong Kong, mainland China, and the Asia–Pacific region; to promote academic exchange; and to disseminate research findings" (2010: 3). According to *HKIAPS at 20*, HKIAPS has published 87 research monographs, 212 papers, two public policy forum papers and 18 USC seminar papers (2010: 90). Its current Director is Professor Fanny Cheung. According to its *Annual Report 2011–12*, HKIAPS had organized 96 conferences, symposia, seminars, public lectures touching on emerging issues on social, economic, and political areas as well as regional development (2012: 2).

After more than two decades of growth and development, HKIAPS has expanded to a staff of around 100 senior and junior researchers and administrative staff. Under the umbrella of the HKIAPS, it houses 10 research centers: (1) The Center for Chinese Family Studies; (2) the Center for Civil Society Studies; (3) the Center of Housing Innovations; (4) the Center for Quality of Life; (5) the Center for Social and Political Development Studies; (6) the Economic Research Center; (7) the Gender Research Center; (8) the International Affairs Research Center; (9) the Public Policy Research Center; and (10) the Research Center for Urban & Regional Development. In addition, it also includes seven strategic research programs: the Chinese Law Program; the Economic Policy Program; the Financial Markets Programs; the Program for Economic Education; the Social Indicators and the Social Development of Hong Kong Program; the South China Program; and the Trade and Development Program. The Telephone Survey Research Laboratory, which has a huge impact on the society, uses social survey to investigate the most current changes in the general public of Hong Kong toward the government and the society. Increasingly, the future research development of HKIAPS is closely evolved with the social and political changes in China as well as the rapid regional development in the Asian Pacific region.

The East Asian Institute (EAI), Singapore

The East Asian Institute (EAI) was established in 1997 to replace the Institute of East Asian Political Economy (IEAPE),

which was originally named East Asian Philosophies (IEAP) and established in 1983. In *Embracing the Past, Unfolding the Future*, the 10-year anniversary publication, the opening page spelt out EAI's mission was "…to promote both academic and policy-oriented research on East Asian development, particularly the political, economic and social development of contemporary China (including Hong Kong and Taiwan), and China's growing economic integration with the world and its political and security implications for the region" (EAI, 2007: 2). Its first director was Professor Gungwu Wang (the former vice-Chancellor of the University of Hong Kong from 1986 to 1995). Currently, its director is Yongnian Zheng who is the former Research Director of the China Policy Institute, at the University of Nottingham. As an autonomous organization, the EAI is governed by a management board of seven people: The Director; the Dean of Faculty of Arts and Social Sciences, the National University of Singapore (NUS); the Dean of the NUS Business school; the Dean of Faculty of Law; the Permanent Secretary of the Ministry of Defence; the Second Permanent Secretary of the Ministry of Foreign Affairs; and the Permanent Secretary of the Ministry of Trade and Industry (EAI, 2007: 8).

One of the key assets of the EAI as a research institute is that it is supported by its own endowment, making it more autonomous and flexible. It has its own library collections of Chinese and English materials on China and East Asia in all social sciences disciplines (the biggest in Southeast Asia). It owns more than 27 892 books including many Chinese yearbooks and statistics. It also subscribed to more than 359 Chinese and English journals and newspapers covering the PRC, Hong Kong, and Taiwan, as well as other microfilms. The EAI has more than 22 in-house researchers and regular visiting fellows and visiting senior fellows stopping by for 3 months to year-long research visits. Visiting fellows are provided with research space, computers, and funding. Among its research activities are weekly seminars, public lectures, and international conferences. In terms of publications, the EAI's *Background Briefs* are well received by Singapore's government as well as other leading research centers focused on policy-oriented analysis of China and East Asia, for instance the Fairbank Center at Harvard University. Other publications include working papers, occasional papers, and bulletins. It has two in-house journals: *China: An International Journal* is an academic outlet for peer reviewed articles, and *East Asian Policy* aims at policy-related papers. The institutes and its research staff regularly publish books and academic papers from their research results (http://www.eai.nus.edu.sg/Publications.htm (accessed 01.12.13.)).

The Institute of Southeast Asian Studies (ISEAS)

The Institute of Southeast Asian Studies (ISEAS) is one of the most celebrated research institutes focusing on Southeast Asia. With support from the National University of Singapore (NUS), the government of Singapore, other civic organizations, and most important of all, the Institute in Southeast Asia, ISEAS has played a key role in informing global academics and governments on every aspect of Southeast Asia, one of the most vibrant regions in the world. The ISEAS was established as an autonomous organization in 1968 by an act of Parliament. The *ISEAS Annual Report 2012–13* clearly points out that ISEAS is "A regional research centre dedicated to the study of sociopolitical, security, and economic trends and developments in Southeast Asia and its wider geostrategic and economic environment" (2013: 2).

Research in the ISEAS concentrates on three core areas: Regional Economic Studies (RES); Regional Social and Cultural Studies (RSCS), and Regional Strategic and Political Studies (RSPS). According to the aforementioned *Annual Report*, there were 22 (in-house and visiting) researchers working in RES, 69 in RSCS, and 37 in RSPC (2013: 10). There are also four units/centers under the umbrella of the ISEAS: The ASEAN Studies Centre (ASC); The Nalanda-Sriwijaya Centre (NSC); The Archaeology Unit (AU); and The Singapore APEC Study Centre. ISEAS is well-equipped with its own library system. As one of the most comprehensive libraries on Southeast Asian studies, ISEAS subscribes to 34 newspapers from different Southeast Asian countries, Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, and Vietnam. In total, it has more than 600 000 catalog records of books and research materials. The Southeast Asian Cultural Collection (SEACC) and Private Paper collections are both key components of the original archives of the library. The library is also undergoing a new development on digitization and automation (2013: 34–38). ISEAS is also featured with its flagship of the ISEAS Publishing House, which published social sciences, cultural, and geographical aspects of Southeast Asian studies. Four major journals under the ISEAS are the *ASEAN Economic Bulletin* (focusing on economic issues and policy analysis), *Contemporary Southeast Asia* (more than 30 years history of covering academic studies on Southeast Asian international relations), *SOJOURN* (covering cultural aspects on Southeast Asian studies), and the *Journal of Southeast Asian Economies* (academic articles on all the 10 Association of Southeast Asian Nations (ASEAN) economies).

The Institute of Social Science (ISS), Japan

The Institute of Social Science (ISS) is one of the oldest social science research institutes in Japan. The ISS was originally established in 1946 within the Tokyo Imperial University under Imperial Ordinance No. 349 (http://www.iss.u-tokyo.ac.jp/assesment/self/1-1.html (accessed 14.12.13.)). Nowadays, the ISS has four main areas of research: the Comparative Contemporary Law, the Comparative Contemporary Politics, the Comparative Contemporary Economics, and the Comparative Contemporary Societies. It houses 52 in-house and visiting researchers. Compared with other research institutes, ISS is different in the sense that it has a clear focus on Japan, by using social science to understand and to serve the Japanese society and economy.

The research projects and centers around the ISS are more centered on application and quantitative social sciences. For instance, the Center for Social Research and Data Archives provides comprehensive data on social science research in Japan. Other newly undertaken research projects aim at tackling the economic, social, and political problems that Japanese people are faced with today. The *Reconsidering Governance*

project, for example, studies corporate scandals and management efficiency. The *Gender Equality and Research Project* looks at work-life balance in modern-day Japan as a postindustrial economy. Other areas of research include the establishment of the Contemporary China Research Base in 2007 to study the economic growth and stability of China. The ISS hosts the flagship journal *Social Science Japan Journal (SSJJ)* and has a very strong library system for its research needs. Recently, the ISS announced that its future direction is to branch out to link up with other international, Asian and Pacific research institutes on various social sciences topics that can improve the study of Japanese society and economy. New collaboration research topics such as 'Contemporary Japanese Society' or 'The Twentieth-century Global System' are some new endeavors. Increasingly, the ISS is trying to establish more educational programs on graduate levels in order to train more social sciences practitioners for the country's need.

The East Asia Institute (EAI), Korea

The East Asia Institute (EAI) of Korea is a relatively new social sciences academy which was established in May 2002. According to the *2012 Think Tanks and Civil Societies Program*, the EAI is ranked 17th of the 45 think tanks in Northeast Asia (2013: 57). According to its own description, "… the EAI was established as an independent think-tank dedicated to developing ideas and formulating policy recommendations on the main challenges facing the region" (http://www.eai.or.kr/type/aboutGreeting.asp (accessed 10.11.13.)). The EAI has a more refined focus mainly on security and regional affairs. Second, it covers Northeast Asia only. By focusing on these two clearly defined areas, the EAI has more of a research focus, while activities and research dissemination can be more carefully tailored with specific impact from the user's points of view.

The scope of the research of the EAI can further be divided into four programs: (1) Peace and Security, (2) Public Opinion, (3) Democracy and Governance, and (4) Education and Human Development. The program of Peace and Security involves different seminars, conferences, and public lectures on regional security issues centring on China, Japan, and Korea's high politics. The Public Opinion Program mainly uses survey methods to come up with regular reports and assessment on global viewpoints, Korean politics, and Korean elections. The Program of Democracy and Governance is used to study Korea's democratic development with a focus on Korea's role in the globalized world. Among the others, the Education and Human Development program aims at broadening the participant base and offering various funding resources to scholars carrying out research with the EAI and its partner institutions such as the EAI Fellows Program, the EAI Global Academy, or the EAI Internship Program. The flagship EAI Fellows Program offers financial support (3 weeks) for established and budding scholars to disseminate original research in two of the partner institutes in Northeast Asia. Increasingly, it has become one of the most prestigious fellowships in East Asian studies. In terms of publications, the *Journal of East Asian Studies* (edited by Stephan Haggard from the University of California, San Diego) publishes peer-reviewed articles (sometimes from the EAI Fellows Program) on East Asian affairs and international relations. The *EAI Working Papers* provides a more policy-oriented East Asian focus on a more substantial scale. The *EAI Issue Briefings* offers a short yet precise assessment of East Asian politics and international relations.

Social Science Infrastructure: European Union (Resourcing and Funding)

Thomas König and Helga Nowotny, Vienna Science and Technology Fund, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Over the past 15 years, European research funding has become increasingly important for social and behavioral research. This article provides an overview of the most important developments, funding opportunities, and ongoing debates related to the European Research Area.

Brief History of European Research Funding

The idea of research funding at European level has been discussed at least since the inception of the European Community. Several programs and instruments can even be traced back to before the 1970s. However, it was only around 1984 that the first Framework Programme for Research and Technological Development (FP) was set up and operationalized by the European Commission, with a moderate budget of 3.5 billion euros over a period of 4 years. The main political objective was to "strengthen the scientific and technological basis of European industry and encourage it to become more competitive at international level" (Andrée, 2009: p. 18). The consecutive Framework Programmes have grown considerably in budgetary size and scope to include the social sciences and even the humanities. The eighth multiannual Framework Programme, Horizon 2020 (from 2014 onward), has an estimated budget of almost 80 billion euros over a period of 7 years. Its ambition spans three 'pillars' of research funding that, together, are intended to boost innovation. The excellence pillar funds fundamental research through the European Research Council (ERC), the mobility program Marie (Skłodowska-) Curie Actions (MCA), and research infrastructures. The second pillar offers funding for industry- and small- and medium-sized enterprise-related participation while the third is devoted to seven societal challenges (for details, see below and Table 1). Though the Framework Programmes are not the only research and innovation funding instruments at European level, due to their broad size and scope, they dwarf all other programs. This finds its expression in the way other, formerly independent programs deal with the superior position of the European Commission's funding clout: They either succumbed, as in the case of the European Cooperation in Science and Technology (COST), which formally retains its independent structure, but fully depends on contributions through the Framework Programmes. Or they dropped out, as in the case of the

Table 1 Pillars and programs of FP8, Horizon 2020 (excluding Euratom)

Pillars	*Programs*	*Approximate budget (in billion euros)*	*SSH share*
Pillar 1: Excellent science	European Research Council[a]	13.095	Approximately 17%
	Future and Emerging Technologies	2.696	/
	Marie Skłodowska-Curie Actions[a]	6.162	Approximately 11%
	European Research Infrastructures (ESFRI and so on)[a]	2.488	Unresolved
Pillar 2: Industrial leadership	Leadership in Enabling and Industrial Technologies	13.557	/
	Access to Risk Finance	2.842	/
	Innovation in SMEs (small- and medium-sized enterprises)	0.616	/
Pillar 3: Societal challenges	Health, Demographic Change and Wellbeing[a]	7.472	Unresolved
	Food Security, Sustainable Agriculture and Forestry, Marine, Maritime and Inland Water Research and the Bioeconomy[a]	3.851	Unresolved
	Secure, Clean and Efficient Energy[a]	5.931	Unresolved
	Smart, Green and Integrated Transport[a]	6.339	Unresolved
	Climate Action, Environment, Resource Efficiency and Raw Materials[a]	3.081	Unresolved
	Europe in a changing world – inclusive, innovative, and reflective societies[a]	1.309	100%
	Secure societies – protecting freedom and security of Europe and its citizens[a]	1.695	Unresolved

European Science Foundation (ESF), an association of national research funders and organizations that perform research, that is closing down its own funding capacities (e.g., Eurocores) after having been transformed into a purely coordinating body, Science Europe.

The Changing Role of Social Sciences in EU Research Funding

The European integration project is mostly driven by the establishment of a common European market. Research funding was thus initially perceived as a way to support the European economic base and its competitiveness by concentrating on science, engineering, and technology. However, immediately after the Maastricht Treaty, the fourth Framework Programme (1994–98) introduced the Targeted Socio-economic Research Programme (TSER). Under the fifth Framework Programme, it was renamed Key Action "Improving the Socio-economic Knowledge Base" (1998–2002) (Kastrinos, 2010: p. 300). According to the final report on TSER, the program was intended "to build up both the knowledge base and research networks for high quality, policy relevant, comparative European socio-economic research at both national and Community level, in order to support sustainable social and economic development" (European Commission, 1998: p. 5). Having funded 365 projects, and invested 267 million euros over the course of 10 years, the fourth and fifth Framework Programmes gave the social sciences a considerable share of the research budget for the first time (although, approximately only 1% of the budget for the two Framework Programmes went to social sciences projects) (Schögler, 2013: p. 59). The sixth Framework Programme widened its scope even further by bringing the social sciences and the humanities together for the first time under the funding stream "Citizens and Governance in a Knowledge-based Society" (Smith, 2003). The funding stream dedicated to research in the social sciences and humanities (SH) under FP7 was consequently called 'Socio-economic Sciences and the Humanities.'

The numbers depicted in Table 2 do not present a straightforward statistical picture of funding dedicated to social and behavioral research; the full extent of social and behavioral research within the FPs remains unclear. This is partly due to the fact that social scientists were invited to take part in and monitor scientific research (Luukkonen, 1998) not classified as 'social research' in early European Commission research funding schemes. In addition, as the FPs grew in size and scope, and as more and more funding instruments were developed, social researchers also participated in research projects in other parts of the FPs, either as collaborators for a specific research task, or (again) as aids in the dissemination of research results, and formulation of policy advice.

From FP6 onward, the situation became even more blurred, as funding for social research became more and more available outside the funding streams mentioned in Table 2. For example, while the mainstream dedicated to SH in FP6 was in priority 7 ('Citizens and Governance in a Knowledge-based Society'), some projects in priority 8 ('Scientific Support to Policies') were also flagged as social research. This trend continued under FP7, and with Horizon 2020, the diffusion or 'integration' of social scientific and humanities research into all topics has even become a political prerogative. Now the European Commission deliberately seeks to abolish the 'silos' of socioeconomic sciences and humanities (SSH) research funding inside its Framework Programme. Instead, SSH will be integrated into all of the societal challenges as 'cross-cutting priorities,' while only one of the seven will be devoted to 'Europe in a changing world: inclusive, innovative and reflective societies,' and hence primarily dedicated to funding social and behavioral research.

In addition to the dedicated funding for research, the MCA provided 4.5 billion euros in mobility grants under FP7. Out of eight panels, two were set up specifically to review proposals from the social sciences (one being called 'social sciences and humanities,' the other 'economic sciences'). Along several funding schemes for individuals and training networks, those two panels allocated more than 500 million euros to social scientists and humanists. Furthermore, within the legal framework of FP7, the ERC was founded. This funding body,

strategically independent but legally bound to FP7, implied a radical shift of European research policy insofar as it followed an approach of scientific excellence as the only evaluation criterion without thematic priorities. The ERC dedicated approximately 17% of its annual budget to individual projects in the SH. As can be seen from Table 3, the ERC has funded 814 projects (2013) and dedicated more than 1.2 billion euros to the SH. Again, these numbers can be misleading since the ERC also funds interdisciplinary projects (König, forthcoming; Nowotny, 2009).

Different Funders, Different Programs, and Different Aims

Since acquiring European funding is mostly a question of 'EU-added value,' namely the funding of research whose value is higher than if were funded on a national level, the initial task of the Framework Programmes was to ask project applicants for collaborative research with project partners across Europe, thereby fostering networking activities (Pohoryles, 2002; Nedeva and Stampfer, 2012). In the meantime, however, the range of activities and programs has increased greatly.

Following their different intentions and aims, we can roughly distinguish four types of funding programs at European level: horizontal programs that support network activities of researchers with similar interests; programs funding research projects along given priorities and policy requests (top–down mode); programs that are open to research projects from all fields and disciplines, usually with individual principal investigators as applicants (bottom–up mode); and initiatives to build up and operate European-wide research infrastructures. In all the four types of programs, there is also funding for social and behavioral research foreseen, although greatly varying in size and visibility.

Beginning with programs supporting network activities, COST (see above) provides funding for European-wide workshops and trainings on specific topics. The oldest funding scheme at European level, COST is now also funded by the Framework Programme. In the same vein, the ESF ran several funding schemes for international workshops, conferences, and so on until recently. The ESF still operates Scientific Review Groups (previously Standing Committees), one of which is dedicated to the social sciences. The Review Group organizes research networking programs, and formulates recommendations related to research policy on social sciences in Europe. The latter function is likely to be overtaken by the newly founded organization, Science Europe. ESF's activities were potentially powerful through linking its policy recommendations with research meetings on related topics and financing preparatory meetings, which later developed into research schemes. Exactly such links may be missing in the new organization, which so far is conceptualized only as a policy and coordinating body.

The European Commission's Framework Programmes primarily fund research projects, not networking activities around research interests (although there are additional schemes for that, too). Under FP7, most grants were allocated under the two funding scheme formats called 'collaborative projects' and 'networks of excellence' (under the previous FPs, the formats had different names, but relied basically on the same concepts). This is also true for the program dedicated to the SH. Up until and including FP7, funding schemes usually required a certain rate of self-financing. Since Horizon 2020 (for details, see Table 1) sets out to simplify the entire European Commission funding administration, only one funding scheme exclusively dedicated to research funding has been set up. Called 'research and innovation actions,' this scheme does not require partial self-financing anymore. However, like its predecessors, it requires at least three different project partners from different parts of Europe to apply within one project proposal. As of April 2014, only the first calls have been published under the new Framework Programme; however, it seems as if most of the funding foreseen for social and behavioral research projects will be in the form of 'research and innovation actions,' too.

Within Horizon 2020, but distinct from the rest of the large project consortia, the mobility program, now called Marie Skłodowska-Curie Actions (MSCA), and the ERC will continue to provide substantial grants to researchers in the social and behavioral sciences. MSCA, while reducing its overall number of funding schemes, will keep its panel structure. Its overall budget will grow to 6.16 billion euros, provide mobility grants for students, PhDs, and postdocs – either to individual researchers or through funding training networks. The ERC will also see an increase in its budget to more than 13 billion euros by 2020. With three main funding schemes – the Starting Grant for young researchers up to 7 years after the PhD, the Consolidator Grant for those establishing their scientific career, and the Advanced Grant for established senior scholars – the ERC will continue to fund excellent researchers. Should the ERC's SH domain retain its budget share of 17%, more than 2.2 billion euros will be spent on basic research projects in the SH.

An important step toward European integration of research infrastructures has been made over the past years with the European Strategy Forum on Research Infrastructures that identifies and prioritizes important research infrastructures across the continent. Of particular interest to the social sciences are the European Social Survey (ESS), the Survey of Health, Ageing and Retirement in Europe (SHARE), and the Council of European Social Science Data Archives (CESSDA). While the three initiatives are of crucial importance to social research in Europe, only SHARE has successfully transitioned into a European Research Infrastructure Consortium (ERIC), a new

legal format of an intergovernmental research entity. Becoming an ERIC guarantees continued funding from the participating members and, at the same time, allows members to raise additional research funding from outside sources. The future of the ESS and CESSDA remains unclear due to a lack of long-term commitment from both national governments and the European Commission.

The Impact of European Research Funding on the Social and Behavioral Sciences: Trends and Critiques

Over the past 20 years, European-level funding increased in importance for the social and behavioral sciences, leaving its mark on the structure of research collaboration, the way the sciences perceive themselves, and how scholars in those sciences feel appreciated. The EU has supported research since the 1970s (Banchoff, 2002: pp. 7–8). Even before the first Framework Programme, programs like COST and concerted enterprises like ESF populated the European research landscape. It is only with the skyrocketing budgets of FP6 and FP7 that the other European programs were dwarfed and some of them even incorporated (see above). The Lisbon Treaty then formally placed science policy on the EU agenda (TFEU, 2009: article 179).

On analyzing European Policy on research funding dedicated to the SH, three observations can be made (Kastrinos, 2010; Schögler, 2013). First, despite the European emphasis on priority-setting and thematic orientations, European research funding is moving more and more toward a 'diffusion-oriented model,' which emphasizes capacity building over a distinct mission. This is also the case with Horizon 2020, whose third pillar – societal challenges – targets the social sciences to build knowledge capacity on broadly defined topics. Second, the EU research programs have emerged as points of reference for the member states, both in terms of those topics (the specific challenges in the third pillar of Horizon 2020) and in the orientation toward diffusion instead of mission. It is already quite clear that the trend will increase under Horizon 2020, if only because this program is now so large that it cannot be ignored by social scientists and policy makers. Already, now we see funding schemes in European member states emerge that are substituting, or complementary to, the individual programs in the third pillar of Horizon 2020. Finally, despite its limited size within the overall FP budget and despite several national funding schemes targeting research in the SH, "in comparative terms this has been the largest targeted programme in Europe" for the social sciences and humanities (Kastrinos, 2010: pp. 301–304).

The European Commission research funding has been long criticized for its administrative burdens, as well as the unintended consequences of requiring research collaboration across national borders. In recent years, social scientists have also voiced misgivings about the limited size of available funding. This is somewhat ironical since, as previously discussed, funding opportunities for social and behavioral research have increased considerably at the European level. One reason for this concern is that funding dedicated to social and behavioral research is still quite small, in terms of absolute size within the overall FP budget (Table 2). At the same time, however, social and behavioral researchers in Europe have started to take European funding increasingly into account, not only because national funds are drying up in many member states, but also because it is recognized that national science policies are increasingly coordinated at, and influenced by the European level. Another reason lies in the fact that in a program that is largely dominated by top–down instruments, research topics are decided in political negotiations. In order to gain a footing, the social sciences would need a proper representational body at the European level. Thus, voicing public complaints has become the preferred mode of arguing on the part of the social science community, instead of proactive bargaining. An attempt to overcome this pattern was made at the conference 'Horizons for Social Sciences and Humanities,' where policy makers, among them high-ranking members of the European Commission's Directorate General for Research and Innovation, and representatives from the SH met and discussed the future of social science and humanities research (Mayer et al., 2013; Schögler, 2013: pp. 176–179). At the conference, the Vilnius Declaration was adopted and brought to the attention of European politicians, underscoring the 'values and benefits of integrating Social Sciences and Humanities' into Horizon 2020 (Hackett, 2014; Mayer et al., 2013: p. 25).

Abstract

This article aims at providing empirical and comparative information on the history of European social science organizations. It looks at two main questions: the factors that contributed to the creation of these organizations, and the differences between them in terms of their membership, organizational structure, and scientific activities. It shows that scientific, academic, and political rivalries played an important part in the creation of organizations and had long-lasting impacts on their development.

Introduction

The creation of European social science organizations is a relatively late phenomenon in the history of sciences in general and of social sciences in particular. When they were founded in the second half of the twentieth century, a wide array of scientific organizations already existed. National scientific academies, such as the Royal Society in England or the *Académie des sciences* in France, had indeed been created as early as the seventeenth century. International forms of scientific gatherings followed closely thereafter. They first took the shape of a few punctual congresses, mostly around the discipline of physics. After 1850, the number of such congresses began to grow at an exponential pace (**Figure 1**) as these gatherings became more diversified at the disciplinary level, with both natural (e.g., physicists, biologists) and social scientists (e.g., demographers, geographers) organizing such events. Several disciplines, such as statistics, set out to hold congresses on a regular basis (Brian, 1989), thereby paving the way for the creation of proper international scholarly associations.

Several international organizations were then created between the mid-nineteenth and late-twentieth century and by 1994, "there were approximately 350 active international science associations" (Schofer, 1999). The late-nineteenth and early twentieth centuries were periods of slow growth, as they saw the creation of about 30% of the associations. In the second half of the twentieth century, international science associations grew in number at an accelerating rate; over 70% of them were founded during that period. As **Table 1** and **Table 2** show, most international social science associations were created during that phase. More specifically, they were founded in the late 1940s or early 1950s, under the auspices of a UNESCO program that aimed at stimulating the expansion of social sciences worldwide (Platt, 1998; Boncourt, 2009). By contrast, it was not until the second half of the 1960s that social scientists set out to create European-wide professional organizations. There were important fluctuations across disciplines: while the European Association for Experimental Social Psychology was founded in 1966, the first European sociology organization (the European Consortium for Sociological Research) was created in 1991. The number of European organizations in a given discipline also varied across disciplines as some of them only numbered one (economics, anthropology, psychology) and others up to three (political science).

Figure 1 Number of international congresses held between 1835 and 1914. Source: Brian, E., 1989. Y a-t-il un objet Congrès? Le cas du Congrès international de statistique (1853–1876). Cahiers Georges Sorel 7, 9–22.

This article aims at providing empirical information on the creation and development of these organizations. It follows a comparative logic to identify common points and differences between organizations and disciplines. It looks at two main questions: the factors that contributed to the creation of European social science organizations, and the differences between these organizations in terms of their membership, organizational structure, and scientific activities. It uses qualitative and quantitative data gathered in the course of a doctoral work on the history of political science (Boncourt, 2011), as well as in the framework of the INTERCO-SSH research project. (The INTERCO-SSH ('International Cooperation in the Social Sciences and Humanities: Comparative Perspectives and Future Possibilities') is coordinated by Gisèle Sapiro and funded by the European Union Seventh Framework Program (FP7/2007–13) under Grant Agreement no 319974 (INTERCO-SSH).) It also draws on secondary sources and most notably from accounts of the history of these organizations written by their founders and past officers (e.g., Kuper, 2004; Moscovici and Markova, 2006).

The Creation of European Social Science Organizations

As **Table 3** shows, a first look at the main characteristics of European social science organizations enables us to outline

ISA	International Sociological Association
IUAES	International Union of Anthropological and Ethnological Sciences
IUPsyS	International Union of Psychological Science
WEA	World Economics Association

several differences between them. First, they were created at different times, as the first of them (EAESP) was founded more than 40 years before the last (EPSA). Second, they differ in terms of the type of funding they benefited from: some associations received public support from national governments, international governmental organizations (such as the European Union) or universities, while others relied on private subsidies coming most often from philanthropic foundations (Ford, Royaumont, Volkswagen, Wenner-Grenn, and European Cultural Foundations). Third, organizations do not have the same geographical origins, as their first president could be based in the United Kingdom, France, Belgium, or Sweden. Finally, these associations have different intellectual orientations as they were conceived as a tool to either facilitate or impede the import of 'American' paradigms and methods into Europe. Following Benoit de l'Estoile's comparative work (L'Estoile, 2008), two types of organizations may indeed be identified: those of a hegemonic nature on the one hand, and those of a pluralistic kind on the other hand. Hegemonic internationalization is defined as "a result of the attraction by the more powerful centre on its own terms. The international idiom, linguistically and intellectually, is the one of the hegemonic centre." By contrast, pluralistic internationalization is characterized as an "endeavor with a strong utopian component: it advocates a meeting ground where in principle all can meet on their own terms. In essence, it strives at creating a kind of non-hegemonic internationalization" (L'Estoile, 2008: 120–121).

A closer look at the history of European social science organizations shows that their founders pursued different kinds of scientific, academic, and political strategies.

1. At the scientific level, most of them aimed at *changing the paradigmatic structure of their discipline* on the European stage by either promoting or resisting 'American' approaches. In

Table 3 Characteristics of main European social science organizations

Name	*Discipline*	*Date*	*Funding*	*First president*	*Orientation*
ECPR	Political science	1970	• Ford Foundation • University of Essex	United Kingdom	Hegemonic
EpsNet	Political science	1996	• European Union • Sciences Po	France	Pluralistic
EPSA	Political science	2010	• Founders' own funds	United Kingdom	Hegemonic
ECSR	Sociology	1991	• European Union	Sweden	Hegemonic
ESA	Sociology	1992	• Austrian Government	United Kingdom	Pluralistic
EEA	Economy	1984	• Central banks • Belgian Ministry of Economy • European Cultural Foundation	Belgium	Hegemonic
EAESP	Psychology	1966	• Royaumont, Volkswagen and Ford Foundations • Ecole Pratique des Hautes Etudes	France	Hegemonic
EASA	Anthropology	1989	• Wenner-Gren Foundation	United Kingdom	Pluralistic

the case of hegemonic organizations, founders strived to follow the American example by importing what they saw as its main strength, that is, its behavioral, statistical, and positivist factions. They criticized European approaches to social matters and claimed that it was necessary to 'catch up' on their American counterparts by importing 'modern' approaches into Europe and subverting dominant paradigmatic power relations in the continent. This was the case in political science, as founders of ECPR claimed that European political scientists did not know enough about 'sophisticated' approaches and methods to be able to interact, let alone compete with their American colleagues (Daalder, 1997; Budge, 2006; Boncourt, 2013). Forty years later, the founders of EPSA followed a similar logic when they felt that ECPR had become too open to sociological and historical approaches to politics, and that a new organization had to be created to showcase political science studies of a deductive and statistical kind. In case of sociology, founders of ECSR were driven by the urge to resist the rise of 'Marxist and phenomenological perspectives' in Europe that, in their view, impeded the development of a dialogue 'of a constructive and productive kind' between European and American sociologists. (Quotes are drawn from an interview with John Goldthorpe, a founding member of ECSR.) Similar logics were at work in the field of psychology, as EAESP was founded in close collaboration with American psychologists with a view of promoting experimental studies and "[improving] or [facilitating] communication between Americans and Europeans" (Moscovici and Markova, 2006). In the case of the European Economics Association, founding members all had close connections with American economists and econometrical techniques, and advocated the strengthening of the European discipline in order to compete with what was being done in the United States.

The creation of pluralistic organizations was guided by comparable mechanisms, as parts of American social sciences were also taken again as points of references. However, this time, American intellectual fashions were to be kept at bay in order for European scientific traditions and specific approaches to be further developed and to offer an alternative to hegemonic paradigms. Thus, the founding members of the European Association of Social Anthropology strongly criticized 'essentialist, idealist, and relativist' approaches that they saw as typical of American anthropology, and sought to "create an alternative space for theoretical debates, an institutional counterweight to American institutions" (Kuper, 2004). Similar dynamics led to the creation of the European Political Science Network whose founders aimed at promoting an alternative to the kind of Anglo-Saxon political science that they saw as typical of ECPR. Founders of the European Sociological Association pursued a similar objective, though in a less-confrontational way: without openly criticizing the nascent ECSR, they sought to create a forum where all kinds of European sociological approaches could find an echo. Thus, while the creation of European social science associations was in part driven by an ambition to provide European social scientists with specific organizational support, it was also linked to an aspiration to influence and even transform the paradigmatic structure of European social sciences, in an either 'hegemonic' or 'pluralistic' way.

2. The founding of European social science organizations was also meant to *play a role in academic competitions* by allowing certain universities, and even certain individuals, to obtain international resources and thus gain additional weight on the national and international stage. This is tangible in several cases. The creation of ECPR has to be understood in relation to the University of Essex's ambition to rival top social science faculties in the United Kingdom (such as the London School of Economics and Political Science, and the Universities of Oxford and Cambridge), in spite of its relatively recent creation (Boncourt, 2013). Similarly, the foundation of EAESP was a way for the Ecole Pratique des Hautes Etudes to establish its reputation in the field of French social psychology, which was at the time dominated by Sorbonne University. It also helped 'University lightweights' of the time to become more recognized in their discipline and academic fields (Moscovici and Markova, 2006). In the case of economics, the creation of EEA was part of a bid to enhance the international reputation of the University of Louvain-La-Neuve and its Center for Operations Research

and Econometrics (Drèze, 2008). In political science, Sciences Po pursued a similar agenda when it pushed for the creation of the European Political Science Network (EpsNet) in 1996, as a rival organization to the well-established ECPR (Bull, 2007; Boncourt, 2011). The founding of European social science organizations thus played a role both on the scientific and the academic stages.

3. Founding members of European social science organizations thus pursued both scientific and academic strategies. However, political agendas also played a role in their undertaking. As they sought to gather external support and funding for their projects, founders were indeed led to collaborate with political actors such as national governments and, more frequently, philanthropic foundations. In the context of the Cold War, these foundations indeed sought to influence European cultural developments, with a view of contributing to the strengthening of transatlantic ties and to the containment of Soviet influence. Studies of the 'cultural' or 'intellectual Cold War' thus show the extent to which these actors played a role in the development of literature, arts, sports, and sciences (e.g., Berghahn, 2002; Sirinelli and Soutou, 2008; Popa, 2011; Solovey and Cravens, 2012). Social sciences were a key part of this project, as foundations invested in the development of European economics, political science, social psychology, international relations and public administration, among other areas. By funding these disciplines, they sought to support the development of social knowledge in order to improve human welfare in the long run. Investing in Europe, rather than in the United States, was a way to help European social scientists catch up on their American counterparts, to deepen transatlantic connections and to strengthen European democracies (Carver, 1986; Saunier, 2003; Moscovici and Markova, 2006; Guilhot, 2011; Tournès, 2011). The Ford Foundation was the main actor in this process in the 1960s. At the time, the Foundation, which had been created in the 1930s with the ambition of enforcing peace and democracy around the world, encouraged the development of European social sciences, which were seen as a good vector for democracy (Magat, 1979; Gemelli, 1998).

Such logics were mostly at work in the case of hegemonic organizations, and philanthropic support took different shapes across disciplines and associations. In some cases, the Ford Foundation and other philanthropic organizations contributed to the structuring of transatlantic and transnational networks, which would later form the basis of European social science organizations. Several European social scientists thus held research fellowships in prestigious American universities such as Yale, Harvard, Berkeley, Princeton, or the Massachusetts Institute of Technology and built on their American connections to create European associations some years later. Most of the founders of ECPR, EEA and EAESP had thus benefited from such fellowships (Daalder, 1997; Moscovici and Markova, 2006). In other instances, the Ford Foundation provided more direct support by funding the new association itself, the University, or the research center that was hosting it. In the 1960s, its policy was indeed to send envoys on tours of some of the European universities and encourage the launching of transnational social science endeavors. As they sought to strengthen transatlantic ties, envoys mostly visited institutions with a track record of interconnections with American social sciences (Magat, 1979; Gemelli, 1998; Drèze, 2008). They notably visited the University of Essex, the University of Louvain, and the Ecole Pratique des Hautes Etudes, thus paving the way for providing financial backing to the creation of ECPR, EEA and EAESP (Moscovici and Markova, 2006; Drèze, 2008; Boncourt, 2013).

Aside of these philanthropic resources, some associations also received support from public authorities such as the European Union and national governments. The involvement of the EU comes at a later stage than that of philanthropic foundations and has implications for both hegemonic (such as ECSR) and pluralistic organizations (such as EpsNet). In the 1990s, the EU indeed sought to promote the structuring of a 'European Research Area.' Rather than pushing for the development of specific paradigms – be they of European or American origins – EU officials followed a geographical objective as they aimed at building scientific bridges between Eastern, Western, Southern, and Northern Europe. The main idea behind the funding of the European Political Science Network was thus to support the development of an organization that would be more closely connected to eastern and southern Europe than the existing ECPR was. In some other cases, national governments also offered financial support to the new organizations. The fact that these subsidies were provided by relatively 'small' countries to associations that held their founding meetings on their soil – ESA in Vienna and EEA in Brussels – could be taken as an indication of the fact that hosting European organizations also constituted a way, however marginal, for these countries to enhance their international profile. Just like philanthropic foundations and the European Union, national governments thus followed their own political agenda when providing funding for the creation of European social science organizations.

4. One last source of funding, albeit marginal, needs to be mentioned. The European Economics Association is indeed unique in having secured funding from central banks. This shows the extent to which the possibility for scholars to obtain financial support for their undertakings is also linked to the existence of strong connections between their discipline and nonacademic professional fields. The very nature of economic knowledge may thus have facilitated access to subsidies.

Several factors thus interacted to trigger the creation of European social science organizations. National and international power struggle and competitions came into play at the scientific level (competition between promoters of different paradigms and methods), the academic level (rivalries between universities) and the political level (competition between countries during and after the Cold War). The importance of these different factors varied according to the intellectual (dominant paradigms and methods) and organizational (existence of other European associations) structure of disciplines.

Table 4 Four most represented countries in each organization (2013)

Italy	Italy	Suisse	Norway	Russia	Italy	Italy

The Development of European Social Science Organizations: Membership, Structures and Activities

After adopting a historical perspective to describe the factors and strategies that led to the creation of European social science associations, this article follows a more sociological logic to describe and compare their current structure. It does so by looking, first, at the geographical scope of their membership. It then seeks to explain common points and differences between membership structures by looking at the organizational settings, activities, and intellectual orientations of associations.

The following tables and figures compile basic data on the current membership of eight European social science organizations (EASA, EASP, ECPR, ECSR, EEA, EPSA, and ESA), EpsNet having ceased to exist as an autonomous association after having been absorbed by ECPR in 2007. (As described below, the European Association of Experimental Social Psychology (EAESP) has been renamed European Association of Social Psychology (EASP).) Table 4 lists the four most represented countries in each association and allows us to highlight common points between disciplines and organizations. Some countries are indeed quantitatively dominant in most, if not all cases: Germany and the United Kingdom systematically count among the three most represented countries, and the United States and Italy also display high representation rates. 'Small' countries such as the Netherlands, Norway, or Switzerland also appear to be more represented than their demographical weight could lead one to expect. By contrast, demographically 'big' countries such as France and Spain are underrepresented. Following literature on the history of social sciences (e.g., Klingemann, 2008; L'Estoile, 2008; Gingras and Heilbron, 2009), one could take these numbers as linked to the linguistic position and the specific modes of internationalization of national fields. The strong presence of Germany and the United Kingdom and the relative overrepresentation of small northern European countries such as Scandinavian nations and the Netherlands could then be taken as a manifestation of their openness to the Anglo-Saxon world. Correlatively, the relative absence of France, Spain, and Portugal could be understood as a consequence of the existence of alternative international arenas where French, Spanish, or Portuguese are dominant languages.

By revolving around the properties of national fields, these interpretations enable us to make sense of the common points between the memberships of European social science organizations. However, they provide no satisfactory explanation for the important differences that divide these organizations. These differences are tangible at two levels. First, the number of countries represented in the memberships of organizations may vary by a factor of three, from 20 in the case of ECSR to 66 in the case of EEA (Figure 2). Organizations also differ at the level of the geographical repartition of their members. Figure 3 illustrates these fluctuations by classifying organizations according to the share of Western members (that is, western European and North American members together) that they gather. The case of EPSA, the most Western and American association in the sample (with 96.5% of Western members, against only 1.3% of eastern European members), thus contrasts sharply with that of ESA (67.7% of Western members against 27.7% of eastern Europeans).

Figure 2 Number of countries represented in each organization.

Figure 3 Geographical breakdown of the membership of European social science organizations (percentages).

These variations may be explained by looking at the specific characteristics of European social science organizations. As they face various constrains linked to the specific organizational, scientific, and political contexts they are embedded in, associations indeed follow different strategies to attract members and cumulate financial resources. These differences are tangible at a very early stage of their development and can be observed at three levels. The first is that of the type of members that associations gather, as most organizations work with individual members (EPSA, EEA, EASP, EASA, ESA) while a few are structured as consortiums of academic institutions (ECPR, ECSR). The second level is that of the geographical conditions that organizations set for membership: while some of them have always been potentially open to scholars based in any continent and country, others such as ECPR, ECSR, and EASP originally restricted their membership to European or even west-European academics. The third level is that of activities organized by associations: while most of them focus on organizing conferences and publishing a journal, some add to these classical activities by developing summer schools (ECPR, ECSR, EASP) and research workshops (ECPR).

This diversity of organizational forms plays a part in explaining variations in the geographical structure of organizations' memberships. Conditions for membership have an obvious impact, and other parameters have an influence as well. Consortium formats may indeed hamper geographical diversification, as non-Western academic institutions experience difficulties in paying their high membership fees. In the same way, costly activities such as summer schools may also limit geographical diversity. The fact that ECPR, ECSR, and EASP gather fewer countries than other organizations therefore appears logical.

However, differences in organizational settings should not be taken as the sole explanation for membership fluctuations. Indeed, as time went on, organizations grew and their structures evolved to become more and more similar. As the organizational environment became denser and more competitive (political science having for example up to three European organizations in the 2000s) and political contexts changed (notably in relation to the fall of communist regimes), associations became more acutely aware of the opportunities for growth and the risk of decline. (The case of EpsNet shows that these risks were more than just speculative as, after having been funded by the European Union, the organization failed to gather enough members to remain independent and was eventually absorbed by ECPR.) On the basis of strategic reviews produced by internal task forces, they adapted their rules and activities by importing from other organizations what they identified as 'best practices,' with the explicit objective of attracting new members. This organizational competition and isomorphism (DiMaggio and Powell, 1991) had two main consequences. On the one hand, it led to a softening of conditions for membership: some associations opened their membership to eastern Europe by reducing fees for scholars located in the region (ECPR, ECSR) and others created 'associate' or 'affiliate' membership categories to allow non-European, and especially American academics to join (ECPR, EASP). On the other hand, organizations diversified their activities by publishing new journals (the *European Journal of International Relations*, *European Political Science*, and the *European Political Science Review* in the case of ECPR; the *Journal of the European Economic Association* in the case of EEA; the *European Journal of Cultural and Political Sociology* in the case of ESA, etc.), organizing additional events and conferences (often dedicated to PhD students) and creating scientific prizes (the Hicks-Tinbergen medal in the case of EEA, the Jean Blondel prize for ECPR, etc.). The organizational landscape thus became increasingly uniform as membership options and activities became more numerous and homogeneous across associations.

Therefore, differences in the geographical scope of organizations must also be understood in relation to other factors. More specifically, the intellectual orientation of associations (hegemonic or pluralistic) also appears to have an impact on membership, as it may be more or less compatible with dominant national paradigms. Correlation coefficients between the representation rate of countries and the intellectual orientation of organizations indeed show that paradigmatic factors are linked to membership variations. The hegemonic character of organizations is first strongly and negatively correlated to the number of countries represented in each association (−0.5). Second, Germany and the United Kingdom are shown to be overrepresented in hegemonic associations, while eastern (Rumania, Poland, Russia), and southern European countries (France, Italy, Portugal, Greece) as well as Finland are significantly overrepresented in pluralistic organizations (Table 5). While detailed analyses of these results would go beyond the scope of this article as they would require careful consideration of national scientific histories, the existing literature tends to indicate that these tendencies are not random: the influence of Bourdieusian theories in France (Bouillaud, 2009) and in

Table 5 Correlation between the representation of countries and the intellectual orientation of each association

Finland (Rahkonen, 2008) and that of historical materialism in the former Soviet Union (Mespoulet, 2007) are indeed at odds with the paradigms promoted by the founding members of hegemonic organizations.

As the founders and officers of hegemonic associations perceived these paradigmatic orientations as having negative effects on their membership, they deployed strategies to try and soften the weight of this stigma. Some organizations therefore changed their names (such as EAESP giving up its 'experimental' label to become EASP) while others claimed to have an ecumenical approach (such as ECPR, a move that eventually led some of its members to opt out and found EPSA). While the impact of these strategies is difficult to evaluate, the very fact that they are deployed shows the extent to which organizations' officers themselves believe in the influence of paradigmatic labels on membership fluctuations.

Conclusion

This short account of the history of European social science organizations shows the value of applying two types of reasoning to the study of scientific internationalization. The first is relational, as the case of European organizations shows that scientific internationalization is linked to the interaction of scientific, academic, and political actors who all pursue specific agendas on the national and international stage. The second is confrontational as the creation of international organizations is here used a weapon to change or consolidate dominant scientific orders.

This account also leads to a call for further studies of the history of scientific organizations. While numerous researchers devote their work to sociological studies of sciences, few have sought to look at the creation, development and activities of local, national, continental, and global scientific organizations. As this short article shows, a look at the history of these associations may provide valuable insight into the changing intellectual and social structures of sciences over time.

Social Science Infrastructure: North America (Resourcing and Funding)

Helmut K Anheier, Hertie School of Governance, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides a brief overview of the most important historical developments, current funding sources, and ongoing debates related to social and behavioral research in North America.

Introduction

The United States has developed a system of funding for the social and behavioral sciences that stands out in terms of scale and scope – scale when measured in monetary contributions for research investments and expenditures, and scope when taking into account the variety of funding sources and research fields. It is a system that involves hundreds of agencies, both public and private, issuing thousands of requests for proposals (RFPs) to universities, research institutions, and think tanks, even individuals. Furthermore, it is a competitive, professionalized system linking grant-seekers and grant-givers, and with nonprofit organizations and businesses operating as intermediaries to help with securing and managing funds. In some aspects it is also a highly individualistic system where philanthropists can decide on supporting some research projects rather than others of perhaps greater scientific merit based on their own preferences. Institutional diversity is the hallmark of the system.

The Canadian system of the social science funding shares many of the American features but is smaller in scale and shows less of an involvement of private foundations and individual philanthropy. Overall, however, the development of Canadian research universities and funding pattern has been more of a public matter than it was in the United States, with the main funding body, the Social Sciences and Humanities Research Council (SSHRC) (www.sshrc-crsh.gc.ca). What is more, the special status of Quebec means that this province has its own governmental funding body, the Fond de recherché de Quebec www.frq.gouv.qc.ca/en/. Nonetheless, the American and the Canadian funding systems show many connections in terms of RFPs open to applicants from either side of the border, joint programs, and common research teams.

The American social science funding system undoubtedly forms the world's largest and is unlikely to be rivaled in the short to medium term by the European system (even with the creation of the European Research Council and massive programs such as Horizon 2020), and the emerging Asian systems, with China being the most likely candidate. What is more, despite the fact that the great majority of funding in the US system remains within the country, the last decades have seen a rise in international activities. In other words, social science funding in North America is a system that operates not only at local, state, and federal levels but is also becoming increasingly international, given the various cooperation agreements signed, for example, between the National Science Foundation (NSF) (www.nsf.gov) and counterparts in Europe such as the German Research Council (www.dfg.de) or the Japan Society for the Promotion of Science (http://www.jsps.go.jp) in Asia.

Not surprisingly, the largest share by far of funding is for the natural and life sciences, including medicine. It is also here that the political–financial link to national defense requirement is clearest, and where the rationale of 'being in the national interest' is more easily made and communicated. In 2011 and 2012 social sciences and psychology represented approximately 5% of all higher education research expenditures (Britt, 2013). As we will see, this share has come under political pressure. We will return to this point in the concluding section after having addressed the historical development of the system as such.

A Historical Overview of Social Science Funding in North America

In the late nineteenth and early twentieth century, the modern American university system took root. This meant moving away from a system of typically small, denominational colleges to a diversified system of major research universities, both public and private, on the one hand, and great variety of colleges on the other. This development was primarily facilitated by both philanthropy and the land-grant movement. Private philanthropy played an especially important part in supporting the emerging social sciences, for example the Russell Sage Foundation which made a large contribution to the study of urban problems in New York City, or the creation of the University of Chicago by the Rockefeller Foundation (see Wheatley, 2010). Philanthropy also provided funding for institutional development such as the creation of the American Council of Learned Societies or the Social Science Research Council (SSRC) (see below). Foundations not only supported research projects, they also established academic departments, and generally helped with the development of individual disciplines such as economics and sociology. They established graduate schools and were instrumental in bringing to the United States highly qualified researchers from Europe, the then center of the world's social science community. One of the most influential US think tanks, Brookings, was established in 1927 through a merger of two sister institutions (Institute of Economics and Graduate School). The think tank, which carries out research on national and international topics, is today financed by a characteristic mix of government agencies, foundations, and leading corporations.

The federal government played only a small role until the 1930s and the inception of the New Deal; however, it began to emerge as a major actor during World War II. As part of the war effort, the government supported war-relevant research, often at a large scale, leading, for example, to the establishment of the RAND Corporation for developing the field of operations research (http://www.rand.org/). It is now next to Brookings, one of the world's leading think tanks. Sociology departments were commissioned to study the morale of combat troops (Stouffer et al., 1949), which resulted in theoretical developments (e.g., reference group theory) and methodology innovations (questionnaire design). Institutions carrying out work in the field of economics, such as the Department of Economics at Chicago, received resources to build and strengthen research capacities, in this case to develop a system of national income accounts to help plan macroeconomic policy in the aftermath of the great depression and in the face of shortages during World War II.

The 1940s and 1950s were also a time when corporations began funding the development of social science methods, especially audience research for radio stations (later also television) and advertising firms. Good example are the influential compilations of research methods by Paul Felix Lazarsfeld and Morris Rosenberg (1955), which owe much to support by media corporations and foundations alike, as did the creation of professional polling firms such as Gallup. In 1941 the National Opinion Research Center at the University of Chicago was established by Harry Field, who had previously worked for Gallup. The center was supported by George Gallup, Elmo Roper, and Archibald Crossley. George Gallup introduced Harry Field to Hadley Cantril (Princeton University), who in turn put him in touch with important social scientists of the time, such as Gordon Allport at Harvard University, to help secure necessary funding. The Marshall Field Foundation then agreed to help establish the Center with a 5-year grant totaling $250 000 (www.norc.org). In the 1960s, President Johnson pushed for the creation of another important US think tank, the Urban Institute, which was launched in 1968 to focus on applied social science research and policy applications. It is funded by the US government as well as private resources (in 2013: 54% federal funding, 39% private funding, and 7% other funding) (www.urban.org/).

In the decades to come, a distinct pattern emerged: different levels and agencies of government and philanthropy provided impulses for specific kinds of research and education and directed their funding streams accordingly, be it the Green Revolution or the Area Studies programs in the 1960s, race relations in the 1970s, health behavior research relating to the spread of HIV-AIDS in the 1980s, civic engagement in the 1990, or Big Data today.

Significantly, greater federal involvement did not replace the importance of local and state funding; on the contrary, it was often accompanied by parallel developments. The funding infrastructure of the state of California is largely a product of the postwar era when federal funding continued to grow. Nor did the establishment of the main governmental funding vehicle, the NSF in 1950, diminish the role of philanthropy. It mostly added to it and the rise of government funding encouraged philanthropy to seek new roles. For example, federal funding of students (loan programs, stipends such as Pell grants (www.studentaid.ed.gov/types/grants-scholarships/pell)) runs in parallel with support by thousands of foundations, often operating at the local level or targeting special applicant pools. Over time, a vast and diverse system of resourcing social science research emerged.

Funding Social Sciences: Portrait of the Main Funding Sources in the United States

Broadly speaking, the funding of the social sciences in the United States comes from four basic sources: government (at the federal and state level), the SSRC, foundations, and corporations. The following section sketches some larger agencies that fund the social and behavioral sciences. It concentrates on federal government agencies and foundations. The selection of the agencies and foundations is not representative and instead serves to illustrate the diversified landscape of funding.

Government

There are several key public agencies at the federal and state levels that sponsor and support the social sciences. Among the largest funders at the federal level are the NSF, the National Institutes of Health (NIH), and the Centers for Disease Control and Prevention (CDC).

National Science Foundation

The NSF was established in 1950 by Congress "to promote the progress of science; to advance the national health, prosperity and welfare; to secure the national defense …" (www.nsf.gov). With an annual budget of about $7 billion (2014), of which $6 billion are devoted to research, the NSF makes up around one-quarter of all federally supported basic research conducted in US colleges and universities.

The NSF is the largest funder of social science research in the United States. It makes up 63% of all federal support for basic research in the social sciences in US academic institutions. The NSF claims that in some fields, including anthropology, archaeology, political science, economics, sociology, and the social psychology, it is the predominant or exclusive source of federal support for basic research and infrastructure development. The Directorate for Social, Behavioral and Economic Sciences at NSF (SBE) supports research that builds fundamental knowledge of human behavior, interaction and social and economic systems, organizations and institutions (www.nsf.gov/dir/index.jsp?org=SBE). Current research and development priorities revolve around topics and issues such as homeland and national security, economic prosperity, integrating research and education and environmental quality. SBE emphasizes research that links different scientific fields, namely cooperations between the behavioral and social sciences and the engineering, physical, and life sciences fields. Moreover, it promotes international scientific cooperations (**Figure 1**).

As the two graphs and the chart below illustrate, funding for the social, behavioral, and economic sciences accounts for a relatively small portion of NSF's overall research budget. In 2013, social science funding totaled $216 million, which is around 4% of the agency's total research budget of $5.4 billion. Clearly, funding for mathematical and physical sciences,

Figure 1 Trends in the NSF budget, 1998–2014. Source: http://www.socialsciencespace.com/2014/03/how-much-nsf-funding-goes-to-social-science/ based on NSF data.

geosciences, computer and information science, and engineering far surpasses the funding available for the social sciences. While the total funding for research and development has grown over the last decades, funding for the social and behavioral sciences has remained relatively stable. However, the 2014 bill to emerge from Congress stipulates a substantial cut in the agency's social science budget.

Generally speaking, the NSF funds research in nearly all fields of science and engineering. It does so through limited-term grants, cooperative agreements, purchase of research equipment for colleges, universities, and other public and private research institutions, and through fellowships for individuals or small groups of researchers. It also supports public and private cooperations at the national and international level. The NSF receives around 40 000 research proposals each year, of which 11 000 are funded. In 2013, approximately 4500 thereof came from the social and behavioral sciences, of which 900 received funding amounting to an annual median size of $45 000. Proposals are usually submitted in response to announcements on the NSF website but may also be submitted independent of such calls.

To fulfill its mission, which is to fund fundamental research in all fields and engineering – except for medical sciences – it uses a merit review process. Proposals are reviewed by a minimum of three selected and external researchers from a national pool of experts. Based on these inputs, NSF program officers will make an award or decline recommendation. The NSF consists of a director who oversees the NSF staff and management and a 24-member National Science Board that establish the overall policies. Each of them is appointed by the US President and confirmed by the US Senate.

National Institutes of Health

NIH is part of the US Department of Health and Human Services and is the primary US research agency in biomedical and health-related matters (www.nih.gov). NIH conducts its own research via its Intramural Research Program (IRP) and funds external medical research via its Extramural Research

Program. NIH with its IRP comprises 27 institutes and centers – among them the Library of National Medicine, an international source for researchers, and National Clinical Center, the world's largest hospital – and employs about 1200 principal investigators and 4000 postdoctoral fellows. This makes the NIH the world's largest research institution for biomedical science (irp.nih.gov/about-us/organization-and-leadership). NIH is also the largest source of funding for medical research in the world (www.nih.gov/about). Overall, the NIH spends about $30 billion annually on medical research. It devotes more than 80% thereof to more than 2500 universities and 300 000 researchers in the form of 50 000 competitive grants (www.nih.gov/about/budget.htm); 10% of the annual $30 billion budget is used to support research activities within NIH's own institutes and centers.

In recognition of the key role played by behavioral, social, and lifestyle factors in the cause, treatment, and prevention of illness and disease, the NIH created the Office of Behavioral and Social Sciences Research (OBSSR) (obssr.od.nih.gov/about_obssr/mission/mission.aspx). Since 1995 it advises and consults NIH scientists and others within and outside the federal agency. The office initiates and encourages studies to evaluate the contribution of behavioral, social, and lifestyle determinants in the development of public health-related problems and sponsors (inter-)national seminars, symposia, conferences, and workshops on state-of-the-art behavioral and social research. Although OBSSR does not have grant-making authority it has been active in organizing and funding a variety of trans-NIH research programs (through transfers to NIH Institutes and Centers). One of its instruments has been the NIH Basic Behavioral and Social Science Opportunity Network (oppnet.nih.gov). NIH-supported behavioral and social research includes research on behavioral and social processes, on interactions between biology, behavior, and social processes, and basic research on methodology and measurement in the behavioral and social sciences. At the individual level this involves studies on behavioral factors such as cognition, memory, and emotion. At the aggregate level it includes studies on the role of social variables such as the structure and dynamics of small groups, institutions, organizations, and larger structures (e.g., demographic, political, and economic factors) in public health-related matters. A list of funding opportunities offered through OPP Net and a number of other behavioral and social science funding opportunities announcements across the NIH can be found here: oppnet.nih.gov/funding-bssr-funding.asp.

Centers for Disease Control and Prevention

CDC is the US public health agency and part of the US Department of Health and Human Services. It is responsible for protecting public health and safety through monitoring, control, and prevention of infectious and noninfectious disease (such as diabetes or obesity), injury, and disability (www.cdc.gov). It does so increasingly with global reach, having established several regional centers (in China, Egypt, Guatemala, India, Kazakhstan, Kenya, South Africa, and Thailand) to detect outbreaks of infectious disease in different geographic areas and attempting to prevent said infectious diseases from being brought into the United States. CDC's activities include detecting and responding to health threats, providing specialized training in field investigations and laboratory methods, preparing and responding to pandemics, detecting and preventing zoonotic (animal–to–human) disease transmission, and providing emergency preparedness and risk communication training (www.cdc.gov/24-7/cdcfastfacts/nationhealth.html?s_cid=cdc_homepage_cdcinaction_001).

CDC implements its mission in collaboration with other US agencies at federal and local levels and other health-related agencies. The CDC thereby provides funding through a range of programs (e.g., Global Health Security Program, the Antibiotic Resistance Program, Food Safety Program, Prevention of Sexually Transmitted Diseases). CDC's annual budget revolves around $6.5 billion (FY 2015), of which it awards nearly 85% in competitive grants and contracts to research organizations and other health-related organizations that contribute to CDC's mission of health promotion through dissemination of health information, preparedness, prevention, research, and surveillance. CDC's mission is subject to congressional legislation.

Social and behavioral scientists help the agency to understand risk groups and the frequency, context, and determinants of risky behavior. They assist in developing, implementing, and assessing the agency's prevention programs (Snider and Satcher, 1997).

Social Sciences and Humanities Research Council

The SSHRC is Canada's federal research-funding agency which promotes and supports postsecondary-based research and training in the humanities and social sciences. Created in 1977, the SSHRC focuses on "developing talent, generating insights and forging connections across campuses and communities" (http://www.sshrc-crsh.gc.ca). SSHRC seeks to promote innovative, interdisciplinary, and international research on social, cultural, technological, environmental, and economic issues and is committed to the goal of ensuring "a better future for Canada and the world" (http://www.sshrc-crsh.gc.ca). SSHR is governed by a council appointed by the federal government to represent the interests of the academic, public, and private sectors. In 2010, following consultations with researchers, postsecondary institutions, and partner organizations, SSHRC made significant changes to its range of funding opportunities by reducing their number, increasing their flexibility, and aligning their objectives under three new umbrella programs: Talent, Insight, and Connection (http://www.sshrc-crsh.gc.ca/about-au_sujet/publications/strategic_plan_2013-16-plan_strategique_2013-2016_e.pdf). While the SSHR has identified six key future challenges, it supports a broad range of topics and disciplines. Funding opportunities include grants, fellowships, and scholarships. In 2012–13 the SSHR-supported research totaled CAN$337 million. SSHR received more than 12 000 applications, of which 5000 were successful.

Social Science Research Council

The SSRC is a nonprofit organization initially founded through an initiative of the American Political Science Association in 1923 (www.ssrc.org). Its goal is to advance the social sciences by fostering innovative, interdisciplinary research, mobilizing different knowledge around important public issues and ethical values, such as justice, prosperity, and democracy, and

lastly to carve out niches in research programs. It seeks to innovate and identify emerging lines of research, so as to promote new fields of research and advancing social change. The SSRC particularly establishes and supports international research and international research collaborations that bring together academics, practitioners, and policy-makers. The SSRC's agenda, in terms of topics and activities, has changed over the course of time and has been responsive to changing problems and needs. In recent years it has focused on issues such as peace-building, human development, understanding the role of religion in the United States, and strengthening a global social science. The SSRC has an annual budget of $23 million. It is sourced from public and private institutions, that is from different (United States and foreign) governments, foundations, and corporations.

Foundations

According to the Foundation Center there are about 86 000 grant-making foundations in the United States (Foundation Center 2012). They bring a sizeable endowment to the table for financing development and research in general. There are several types of grant-making foundations, most of them (78 000 that is, 91%) being independent foundations. In 2012, independent foundations held assets worth $584 billion. Only about 2600 of the grant-making foundations are corporate foundations. They held about 6% of all assets (http://data.foundationcenter.org/#/foundations/all/nationwide/total/list/2012).

As outlined above, foundations have played a critical historical role in the setting up of the American university system. They have done so directly through the funding of specific projects and indirectly through the funding of higher education and teaching more in general. As such, they have also reinforced the idea of research and teaching (Wheatley, 2010, p. 74).

Although major funding projects by foundations can be found in the realm of the natural sciences, in 2011 there were nearly 300 foundations with a grant value of approximately $240 million financing social and behavioral science projects (http://data.foundationcenter.org/#/fc1000/subject:social_science/nationwide/top:foundations/list/2011).

Alfred P. Sloan Foundation

The foundation of the former President and Chief Executive Officer of General Motors Alfred O. Sloan has total assets of $1.7 billion, with around $20 million spent on social science/interdisciplinary projects in 2011. Driven by the idea that a "reasoned and systematic understanding of the forces of nature and society, when applied inventively and wisely, can lead to a better world for all," the Foundation focuses on science, technology, and economic institutions (www.sloan.org). It funds basic natural science research programs for a better understanding of digital information technology. Furthermore, it promotes access to higher scientific education and advances the public understanding of science, technology, and economics. The social science subprograms have a strong emphasis on economics and deal, amongst others, with the economic implications of the great recession and behavioral economics/household finance.

Andrew W. Mellon Foundation

The Mellon Foundation was established in 1940 as the Avalon Foundation. In 1953 it merged with Old Dominion Foundation and in 1969 changed to its current name (http://www.mellon.org). It focuses on higher education and scholarship, scholarly communications and information technology, art history, conservation, museums, and performing arts. It has total assets of $5 billion, with around $16 million spent in the social sciences. The Foundation supports a wide range of initiatives to strengthen the institutions that sustain scholarship in the humanities and 'humanistic' social sciences, primarily research universities but also a small number of centers for advanced study and independent research libraries. There are several fellowships like the Charles A. Ryskamp Research Fellowships or The John E. Sawyer Seminars on the Comparative Study of Cultures.

The Rockefeller Foundation

The Rockefeller Foundation was founded by John Rockefeller, his son John Rockefeller Jr., and Frederick Gates in 1913. The Rockefeller Foundation's historical mission is "to promote the well-being of mankind throughout the world" (www.rockefellerfoundation.org). One of its core objectives is to finance education, in particular higher education without discrimination by race, sex, or creed. Nowadays it primarily supports work that expands opportunity and strengthens resilience to social, economic, health, and environmental challenges. As an example, the Rockefeller Foundation Bellagio Center promotes interdisciplinary research through conferences and residency programs. The foundation has assets amounting to $3.6 billion. The value of grants made to the social sciences in 2011 was $8.8 million.

Ford Foundation

Founded by Edsel and Henry Ford, founder of the Ford Motor Company, the Ford Foundation began as a local philanthropic organization in 1936. It grew to be one of the largest and most influential foundations with 10 overseas offices, providing loans and grants of over $16 billion worldwide (http://www.fordfoundation.org/). Its mission is to "strengthen democratic values, reduce poverty and injustice, promote international cooperation and advance human achievement." With assets totaling $11.2 billion and a total of $7 million spent in the social sciences in 2011, it funds research that supports the work of different initiatives as well as public policy analysis that informs advocacy and public mobilization. Causes supported by the Ford Foundation range from 'democratic and accountable government' to 'gender, sexuality and reproductive justice' to sustainable development and human rights.

Bill & Melinda Gates Foundation

With total assets of around $37 billion, the Bill & Melinda Gates Foundation is one of the largest foundations worldwide.

Established in 1994 as the Wiliam H. Gates Foundation, it merged in 2000 with the Gates Learning Foundation to become the Bill & Melinda Gates Foundation. Driven by the understanding that every life is of equal value, it focuses on extreme poverty and poor health at the global level as well as failures in the US education system (www.gatesfoundation.org). In terms of North American social science funding, its focal point lies on research connected to education policies as well as migration.

Summary and Outlook

In the previous edition of the Encyclopedia for Social and Behavioral Studies, S.E. Cozzens came to a rather positive conclusion regarding the future of research in the United States. However, this prediction may have underestimated the tensions that are embedded in the American funding system, especially in the context of social and behavioral studies.

There is a fault line inherent in the US system, which is shaped by political, economic, and academic influences. The last few years have witnessed a fierce debate about governmental funding for research and development in the social science research area. Several Republican Members of Congress accused the NSF of misusing tax dollars for grants spent on social and behavioral studies research. The debates culminated in the bill on 'The Frontiers in Innovation, Research, Science and Technology (FIRST),' which was brought to the US House of Representatives in the 2013–14 session. This bill pronounces a clear priority of research and development in the 'basic research fields,' which are identified as being biology, chemistry, physics, computer science, engineering, and mathematics, and simultaneous cutbacks in funding for social and behavioral studies unless they are 'in the national interest' however defined. There are, though, politicians who fear a danger in the cutback of funding for social and behavioral studies, as the discipline covers important research areas such as terrorism, disaster management, global health, and others, and researchers in the field conduct significant long-term studies, for example on voting patterns.

What is more, there is also a major debate about the relevance and impact of the social sciences in both the United States and Great Britain, which is led, amongst others, by Patrick Dunleavy of the London School of Economics. Dunleavy strongly emphasizes the impact and contributions made by the social sciences to public policy issues, economic success, and to the awareness of the public in terms of understanding policy issues and social and economic changes.

It seems that the inherent tensions in the complex and diversified funding system have come to the forefront. The coming years will see if the system can accommodate the preferences of the various stakeholders (the academic community, government, political parties, philanthropy, and corporations) as well as it did in the past.

Abstract

Academic associations expanded greatly in scope and diversity in the last 50 years, fueled by rising citizen demand for higher education, the increase in faculty positions and doctoral programs, and the growth of government funding. But growth is now much more difficult due to increased competition, fewer tenure track positions, the decrease in public funding for higher education, the shift in foundation priorities, and the digital revolution, which has given scholars a myriad of ways to network and access important information. Consequently, academic associations need to rethink their value proposition for membership, with important implications for their programming, advocacy and public engagement roles, and governance. This article focuses on academic associations in the social sciences and offers recommendations and next steps as they seek to remain relevant to the scholarly community, policymakers, and the citizenry.

Introduction

Academic organizations have played a crucial role in the growth of higher education in countries around the world in recent decades. These organizations include associations of scholars, coalitions representing higher education interests, research institutes, and think tanks. They often work in concert with government agencies to support the increase in the professoriate, and give citizens more opportunities in higher education. Associations grew in numbers and influence at the same time as faculty employment, student enrollment in higher education, and the number of doctoral programs were increasing. But academic organizations in the social sciences are facing a rapidly changing social and political environment, creating uncertainty and new challenges to their mission, strategic priorities, and role in public policy. This article focuses on academic associations in the social sciences, such as the American Political Science Association (APSA) and the International Studies Association (ISA) in the United States, although attention will also be devoted to other important academic organizations. The article will offer a historical perspective on academic associations, focusing on the social sciences, followed by an examination of the key shifts in the political and social environment of academic associations. The article then offers an analysis of the next steps for academic associations as they seek to remain relevant to the scholarly community, policymakers, and the citizenry.

Growth and Opportunities

Universities have existed for at least several 100 years with many universities in Europe founded in the Middle Ages. But academic associations are a phenomenon that is much younger, with many of the large disciplinary associations established in the late nineteenth and early twentieth century. For instance, the APSA was founded in 1903, reflecting the growth of universities in the United States and the trend toward greater professionalization in society at large. Nonetheless, these associations lacked substantial organizational formality and were often unincorporated groups of scholars who used the association to provide networking opportunities and professional advancement. Associations functioned like loose networks of scholars who came together for academic meetings and to discuss important disciplinary issues. For most of the twentieth century, the major disciplinary associations such as APSA, the American Sociological Association (ASA), the American Anthropological Association, and the American Economic Association (AEA) largely had a monopoly on membership in their particular field or discipline: academics needed to join one of these organizations in order to obtain access to key disciplinary journals, which were owned by the association. Moreover, associations offered an annual conference or summit, for which attendance was essential to upward mobility in many professions. Further, leadership in associations was critical to professional development and advancement especially at large elite universities. Indeed, the larger elite universities tended to dominate professional associations in terms of leadership, journal editorship, and committee participation. Associations were thus intermediaries between individual faculties, students, and important content (e.g., peer-reviewed articles). Moreover, they provided access to faculty job listings.

Social science associations also benefited from the general growth of higher education in the mid to late twentieth century. In the United States, federal funding of higher education, especially in the sciences, began to take off during World War II. This type of federal funding continued after the war and helped to build university infrastructure and fuel university expansion. But federal funding rose sharply in the 1960s with the overall growth of the federal role in public policy. A wide variety of federal funding programs flowed to universities: research grants in the social sciences, loans and grants for college attendance, and direct support for doctoral education. Overall, more extensive federal funds greatly increased employment opportunities in the social sciences. Consequently, academic associations grew accordingly: APSA membership, for example, rose from 7624 individual members in 1964 to 13 663 members in 1970. Other associations experienced a similar increase in membership (APSA, 1970).

Throughout this period, social science associations tended to pursue a traditionalist view of the proper function of

a learned society. The focus of association activities was on the annual conference, the publication of association journals, and overall support for research and teaching. Associations rarely engaged in advocacy; thus they did not actively strive to influence public policy, except for issues that directly related to the discipline such as government research funding. And even in these cases, the advocacy was often delegated to third-party coalitions and associations. Also, efforts to recruit and organize members were quite limited. Indeed, associations did not need to really devote substantial time and resources to member recruitment because membership rolls were rising without any effort on the part of the associations, thanks to the expansion of higher education institutions, fueled by increased federal funding, and demand for higher education on the part of the baby boom generation.

A Shifting Context for Academic Associations

In 1976, during the presidency of Jimmy Carter, the social and political environment for higher education began to change. The economy was plagued by slow growth, high inflation, and stagnant wages, leading to fiscal austerity by the government. Many grant programs established in the 1960s were cut quite sharply. Universities responded to cutbacks in public funding by reducing the number of faculty openings and, in some circumstances, eliminating smaller departments and faculties, especially in the social sciences and humanities. Membership and attendance at the annual conferences declined, albeit to varying extents depending on the association. Moreover, the Reagan administration in the 1980s initiated a long-term restructuring of the federal government, which caused a shift away from extensive federal support for higher education. Moreover, universities raised tuition fees and more directly competed with each other for students, as well as public and private funding. Yet, the number of individuals receiving doctoral degrees in the social sciences continued to rise during the 1980s and thereafter. But the number of applicants per job opening increased substantially as the growth of individuals with doctoral degrees outpaced the number of faculty openings. Membership growth in many associations stagnated as more individuals with doctoral degrees did not land a job in the academy.

Although membership growth in academic associations hit a plateau, associations still retained their monopoly on the university-based scholar, who needed to participate in academic associations for professional advancement. Despite the lack of growth in membership, the business model of academic associations continued to be sustainable: most of the association revenue was generated by membership and conference registration fees; special programs were externally funded by federal and foundation grants; and private philanthropy tended to be limited to special fund-raising campaigns rather than for operating funds. Formal development efforts were thus quite targeted. In short, associations had sufficient revenue to serve their members, albeit at a lower level than earlier periods.

The central position of the large disciplinary associations for professional social scientists began to erode with the establishment and growth of more specialized associations. Many of these younger associations were also interdisciplinary, attracting individuals from a wide variety of disciplines. Good examples include the ISA, the Association for Public Policy Analysis and Management, and the African Studies Association. But many regional associations were created as higher education expanded at the national and subnational level. These newer associations were important because they provided networking opportunities, as well as access to research and publications that had long been the province of the large disciplinary associations. The multiplying number of associations also reflected the increasing diversity of interests within academic associations. In earlier decades, associations were, as previously noted, relatively small, and the range of teaching and research interests was modest. But a variety of trends intersected to increase the diversity of the disciplines including globalization; more openness to new and different research approaches; and changes in association rules and procedures to promote greater representation of different interests. The expansion of higher education also provided more incentives for faculties to publish and network. Being more flexible, smaller associations offered an attractive alternative to large associations, especially for faculties from nonelite institutions.

Changing Landscapes for Associations

The Digital Revolution

The proliferation of smaller and more specialized associations was greatly abetted by the digital revolution and the advances in the World Wide Web. With the creation of email and other Web-based technological innovations, communications among like-minded scholars became easier, cheaper, and faster, reducing the transaction costs of creating a new association. Web-based communications also facilitated the sustainability of these newer associations.

Over time, new associations supplanted the large, disciplinary associations as the primary academic associations for some scholars.

The digital revolution has also fundamentally transformed the relationship between associations and their members. Scholars can now access association journals through their university library systems, effectively decoupling membership from journal access. Secondly, the Internet has made it far easier to network with colleagues, publicize member research, and learn about new research. Many political scientists, for example, are actively engaged in blogs where important substantive political analysis is posted and discussed. Scholars can now quickly disseminate their papers to colleagues around the world and conference attendance is no longer necessary to network. Thirdly, the digital revolution has made it possible to implement new evaluation tools for faculties. In the past, conference participation through a paper presentation or panel chair role was considered an important signal of your standing in the profession. Publications in university press books and peer-reviewed journals were, of course, also considered important for a scholar's prospects for promotion. But the advent of Google Scholar and journal impact factors that measure the utilization of published journal research have created new evaluation tools for faculties that reduce the value of conference participation as a signal of research quality and

scholarly prominence. Fourthly, the digital revolution has directly and indirectly encouraged the increase in new academic journals outside the orbit of academic associations. In earlier decades, larger disciplinary associations controlled the major journals in their field and received royalties from journals to support the association. By reducing operational and start-up costs, the digital revolution promoted the creation of new journals. One of the more notable examples is the new concept of open access journals that are entirely online, and allow any person to access the journal content. Many of these journals also publish articles on a rolling basis, meaning that accepted articles are placed online shortly after acceptance.

In its essence, the digital revolution has changed the production and dissemination of knowledge because scholars can easily access scholarly content that can help them in their own research and teaching; further, easy access to the Web also facilitates greater diversity in the production outlets of knowledge.

Public and Foundation Funding

The digital revolution of the last 20 years has coincided with an altered relationship between universities and their faculties, with important ramifications for academic associations including social science associations. During the mid to late twentieth century, the university infrastructure grew and faculties were rewarded with more positions, including assurances of tenure and decent salaries. But governments have encountered serious fiscal problems in recent years, leading to cutbacks in public support of higher education. As a percentage of the total number of faculty positions, the number of tenured positions has dwindled around the world, including the United States, albeit to varying degrees.

Support for research and conferencing has also become more constrained, especially at nonelite institutions. In the United States, private foundations provided substantial grants throughout the 1960s and thereafter to stimulate the expansion of the higher education infrastructure, including universities and academic associations. Associations received grants to hire faculties and launch new programs and departments. For example, a wave of public policy graduate programs was started in the 1970s with seed money from leading foundations. Similarly, many universities created geographically specific programs such as Russian studies or Latin American studies with federal and foundation grants.

Foundation funding was critical in launching and expanding the intermediary infrastructure of higher education as well. Starting in the 1960s and 1970s, many associations received funding to launch new initiatives on topics such as professional development and special conference programing. Moreover, leading national foundations supported the creation of new associations and interest groups to represent universities and higher education. In the field of nonprofit and philanthropic research, for instance, foundation funding directly led to the establishment or expansion of several intermediary organizations: the International Society for Third Sector Research and the Independent Sector, the Association for Research on Nonprofit Organizations and Voluntary Action, the Aspen Institute research fund, and the Urban Institute research program on nonprofit and philanthropic organizations. Over time, though, the expanded infrastructure produced greater competition among these organizations. Newly established, more specialized associations now competed with the traditional disciplinary associations for members and the new research programs at think tanks such as the Aspen Institute, the MDRC, the Urban Institute and Mathematica now competed for federal and private foundation contracts and grants.

This competition has intensified as foundation priorities have shifted in the last 10–15 years. After years of building the academic infrastructure, many leading foundations have refocused their funding priorities on more applied fields such as early childhood education, school reform, youth mentoring, poverty alleviation, and health prevention. The Gates Foundation, the largest foundation in the world, is a good example of this general tendency among contemporary foundations: a keen interest in directly addressing social problems with a relative disinterest in traditional academic research unless it has an applied component (such as direct implications for policy and practice.)

This shift in foundation grant practices has had important ramifications on the business plans of academic associations and other organizations, such as think tanks. Foundation funding helped to cross-subsidize operating expenses including the administrative overhead of associations. With the decline in foundation funding, academic associations such as APSA are, by necessity, forced to be more reliant on other sources of revenue including member fees, conference registration fees, and earned income such as building rent and corporate sponsorships. Creating a viable, sustainable business strategy is challenging, given the current competitive climate for members and grants. As discussed previously, large associations have a sizable membership base, which allow them to generate significant revenue from membership fees; yet, these fees have risen over time and many universities have reduced their funding for conference travel and association membership. Further, large associations face competition from smaller associations who typically have less expensive fee structures. Consequently, large associations cannot easily raise charges or conference registration fees to compensate for declines in external funding.

The change in foundation funding priorities has also had ripple effects on other types of academic organizations. Many intermediary organizations have been forced to restructure their operations and try to generate new sources of revenue. Think tanks and research firms have adapted by seeking new grant opportunities, partnering with other organizations, and broadening the scope of their research activities.

Smaller and younger membership associations face a similar dynamic as the large disciplinary associations such as APSA and ASA, but they are more reliant on their annual or biennial conference for revenue. The conference generates income through registration fees and encourages new memberships and renewals. Even in this scenario, conference fees may only generate enough income for a relatively small staff, complicating efforts to diversify the revenue base and recruit new members. Moreover the proliferation of associations and conferences has in turn meant that it is more difficult to use the conference for significant boosts in

revenue, without substantive changes in paper and panel acceptance policies.

Federal Policy

Changes in foundation priorities have occurred at the same time as important shifts in federal funding of research and teaching for higher education institutions and the social sciences in particular. Associations themselves have never been big recipients of federal grants, although they did receive funding for training, education and exchange programs in the post-1960s era. Federal funding supported the research of association members, especially in the social and behavioral sciences through the National Science Foundation (NSF), as well as other federal agencies. The opportunity to sit on federal grant review panels was a prestigious honor and the grant application process was very competitive. The annual conference of academic associations provided a vehicle for networking on possible grant applications; indeed, the annual conference often provided an opportunity to plan a grant application or showcase the results of federally funded research. With federal funding in decline, academic associations lose an incentive, both directly and intangibly, for membership and participation in associations. Reduced federal funding also means fewer faculty positions and fewer opportunities for scholars to be employed in think tanks and research organizations.

More broadly, the drop in federal grant funding for higher education has been accompanied by broad skepticism and even hostility toward social science research, peer review, and the effectiveness of higher education. Lawmakers have questioned the objectivity of the peer-review process for federal grants and the value of social science research for policy-making. In the case of political science, for instance, restrictions were placed on NSF funding to grants in national security or economic research, which was in the interest of the United States. These restrictions, the so-called Coburn amendment, were removed in 2014; however, skepticism in Congress toward social science research remains. Also, state lawmakers have increasingly demanded that public universities receiving state funds improve their productivity as measured by the time to graduation, student enrollments, and faculty class time. State funding of higher education has also been in decline throughout the country, albeit to varying degrees.

The decline in public funding and the overall competitiveness of the resource environment for higher education has squeezed the finances of many universities. One response by universities is to hire more adjunct and temporary faculty positions as a percentage of the total professoriate. Indeed, aspiring scholars are likely to encounter much more contingent employment prospects than earlier generations of scholars. In turn, this development has at least indirectly affected academic associations: with fewer full-time faculty positions, associations face recruitment and retention challenges for potential members.

The marked change in the political and academic context of academic associations also pushes associations and other academic infrastructure organizations to rethink their relationship to governments and the policy-making process. When government funding was rising, associations worked in partnership with government agencies; aggressive lobbying and advocacy for associational concerns was largely unnecessary. Indeed, academic associations largely avoided government relations staff, relying instead on third-party coalitions and networks to advocate their issues. Yet, the cutbacks have pressured associations to be more assertive in their advocacy and invest additional resources in government relations.

Further, associations now face new emergent policy issues related to the globalization of education. The international membership of large US-based academic associations such as APSA has been on the rise since the 1960s. It is much easier now, due to the Internet, for scholars to connect with each other around the world. Moreover, higher education has expanded throughout the world. This means that important questions related to academic freedom, such as the restrictions placed on scholars and their research in foreign countries, is arguably a more urgent concern of US-based associations. Also, advocacy on behalf of foreign scholars is much easier, due to the ability of associations and their members to rapidly disseminate information on academic freedom concerns throughout the world. For instance, the detention of a scholar in a foreign country could easily prompt an effort by academic associations to write letters to foreign embassies and post-information on the association Web site to protest the detention.

Advocacy such as trying to influence public officials and public engagement requires academic associations to be mindful of their tax status and the regulatory limitations on their ability to do lobbying. Most US associations are incorporated as 501 (c) 3 public charities; as a result, they face restrictions on their ability to do lobbying, since this is defined as direct influence on legislation by contacting lawmakers and members of congress by the federal Internal Revenue Service. Thus, academic associations incorporated under this provision of the tax law are prohibited from engaging in partisan activity and have a budget ceiling on lobbying expenses. But most academic associations rarely get close to their spending limits.

The Future of Academic Organizations in the Social Sciences

As discussed throughout this article, the more turbulent environment for academic organizations has required them to rethink their strategic priorities and relationship to members, government, and the citizenry more generally. Academic associations will need to create a different mix of incentives for their members to attract their initial enrollment and their continued participation. This effort requires associations to think differently about key aspects of their operations: annual conferences, journal publishing, member benefits, and their Web sites and social media presence. In essence, associations need to provide more value to their members in order to sustain their membership and participation and use current trends, such as the digital revolution, to their advantage. For example, the number of conferences has proliferated so greatly that each association needs to make their conference as distinctive as possible. Useful innovations in association conferences are live streaming of conference events, posting podcasts on the association Web site, extensive media coverage, greater use of social

media, and experimentation in panel and presentation format. These innovations also help ensure that the conference content lives beyond the 3 or 4 days of the actual summit. While the conference will always be a one-time event, the content itself can be made accessible to conference attendees, the wider academic and policy community, and interested citizens. Put another way, associations will need to think more strategically about their meetings, and their connection between the format and the content, as well as the association goals regarding membership and revenue. Even the location of the conference will be important, especially for smaller associations, since membership is often tied to conference attendance, and smaller associations are more dependent upon conference revenues to generate surplus revenue to support the administrative infrastructure.

Associations have also relied on royalties from their journals to support their operations. While journals were a powerful incentive for membership in the association, the movement to open access journals and the limitations on library budgets puts pressure on these types of revenues. Yet, open access journals and online journals offer associations more opportunities to create new and/or niche journals that might be of interest to members (or potential members). Again, larger associations are in a better position to provide these new publications.

Another important method to increase interaction and membership is through an active and engaging Web presence. Academic associations, like other nonprofit organizations, need an accessible and attractive Web site that provides a portal into the various benefits of membership. The Web site is also critical to networking, advocacy, public engagement, and increasingly to fund-raising. The Web site could be used for blogging, recruiting new members, and posting important news of the profession. Associations can also partner with other organizations and Web sites to link members with additional content and information.

The successful recruiting and retention of members will require academic associations to think creatively about the structure of membership benefits. The specific benefits will vary depending on the association and its own institutional history, but they should be linked to the strategic priorities of the association. Further, benefits should draw individuals into registering as members and maintaining their membership. Associations may also want to consider a tier membership structure that offers different levels of benefits depending on the amount of the membership fee, a departure from the current standard model in associations that provide all benefits for one price (although some associations have a graduated income structure).

The larger disciplinary associations have the advantage of already having a substantial membership base. The AEA, for instance, had over 18 000 members in 2013 (AEA, 2014), while the APSA had over 13 000 members (APSA, 2014). Smaller associations have less overhead, though, and in some cases they operate more informally. Regardless of the size, though, growth in membership is challenging given the current environment (see ACLS, 2014). Thus, all associations face incentives to generate nonmember dues revenue. Some associations, for example, own property and can thus generate income from tenant rents. An association may also build an endowment to support general program operations or specific initiatives or projects. Or the association may try to raise additional philanthropic support from individuals, but this task is quite difficult since most philanthropic support for academic associations is pledged for a specific purpose such as a scholarship award in the name of a prominent association member.

The successful strategic positioning of academic associations will also hinge on the concerted attention on the organizational governance structure. Importantly, academic associations have some unique features that distinguish their governance structure. Firstly, many board members are appointed due to their prominence in the discipline or subfields, rather than their particular skills (such as budget experience) or access to external resources. Secondly, membership of association boards and committees tends to be tied to disciplines, and often does not include relevant stakeholders such as foundation leaders, representatives from research institutions, or organizations representing higher education interests. Thirdly, the boards or councils of associations tend to meet relatively infrequently. Thus, it can be difficult for associations to respond quickly to emergent development, either in the organization or externally. Moreover, the small size of staff of some associations can complicate organizational governance. Considering these structural considerations, academic associations need to think very carefully about the composition of the council and committees, including the selection process, terms, and relationship to the executive staff, to ensure that the association's structure provides adequate oversight and the ability to be flexible in decision-making.

The altered context of associations places them in the spotlight as representatives of higher education and professoriates. Consequently, associations are expected to fully engage in complicated issues related to their own membership structure, as well as higher education more generally. Indeed, a host of complicated concerns now face higher education including the growing number of adjunct and contingent faculties, academic freedom for domestic and foreign scholars, decline in public funding, and rising demands for more accountability in higher education. In response, associations may invest more resources in government relations and advocacy, especially more staff resources. Nevertheless, this step is unrealistic for many small organizations that do not have substantial resources to devote to advocacy, government relations, and public engagement. As an alternative, associations can work with intermediary coalitions and other academic institutions to further their goals and priorities.

The policy and regulatory environment is complicated but it also provides ample opportunity for academic organizations to effectively advocate, if they devote resources and priority to it (also Berry, 2004; Pekkanen et al., 2014). Further, some national associations, which have focused on supporting conferences and service members, may need to be more forceful and visible in their advocacy on behalf of higher education. Increasing collaborations among the various actors in the association and coalition infrastructure is also essential, given the scarcity of new resources. Partnerships with organizations and interest groups involved in K-12 education could also be quite helpful for academic associations with a university-based membership or a focus on higher education.

Advocacy to influence public policy including grant program funding and regulations is also closely related to public engagement. In recent years, social scientists have been criticized for their disconnection from real-world problems and the inaccessibility of their research (Kristof, 2014). To address this critique, social scientists will need to do a better job in engaging with the citizenry and the policy process. This effort should include greater dissemination of academic research through social media, more focus on translating academic research for general audiences where appropriate, and establishing new outlets for social science research that go beyond traditional peer-reviewed academic journals and books. On this public engagement front, academic associations can provide key support and encouragement to individual members. Working with other partners such as academic publishers, universities, and coalitions, associations might also help to devise new venues and opportunities for greater public engagement by their members.

Given that there are multiple actors in the academic infrastructure at a time of shrinking, or stagnating, resources, it seems likely that organizational consolidation is likely to occur, especially among smaller coalitions and associations with overlapping missions. Larger research firms may also absorb smaller organizations that lack a diversified revenue base and more sustainable funding. Smaller academic organizations may also need to find a more financially stable partner (such as a university).

Conclusion

Academic associations expanded greatly in scope and diversity over the last 50 years, fueled by rising citizen demand for higher education, the increase in faculty positions and doctoral programs, and the growth of government funding. This article has discussed the changing infrastructure in which associations are operating. Yet, academic associations remain important for professional advancement. Doctoral students are socialized into the discipline by participation in meetings, and they can make valuable contacts and receive useful feedback on their research; they can also learn about job openings and the process of successfully landing a position. Young faculties with university positions may find participation in association conferences very helpful for raising their visibility within the profession. More senior faculties engaged in active research projects, especially at the elite institutions, will also continue to find conferences professionally valuable. Nonetheless, academic associations need to rethink their value proposition for memberships. In many associations, this process is already underway. Generally, associations need to restructure their governance in order to respond to their members more effectively, as well as to broaden their operations to include the wider public, educators, public and private funders, and policymakers.

Associations would also be well served by thinking of their organizations as part of a community of scholars and advocates concerned about higher education. The natural tendency of many nonprofit organizations is to focus on internal issues connected to organizational maintenance; but academic associations should be striving to connect important policy goals related to higher education, including pedagogy, academic freedom, and decent employment conditions, to their plans for sustainability. Moreover, the engagement of academic associations in these issues would also be an incentive for individual scholars to join and remain members of associations. Policy advocacy and participation in a shared community of organizations concerned with higher education would also elevate the profile of associations, help broaden the support for the organizations, and potentially increase the attractiveness of associations to donors. In the long run, associations need to actively strengthen the overall infrastructure of higher education including research enterprise and pedagogy, steps which will benefit their academic members, and greatly enhance organizational vitality and sustainability.

Abstract

In recent years, social and behavioral sciences have become a standard element in higher education, in public debate and media coverage, in policy-making, administration, and corporate management. The increasing importance of social and behavioral sciences for the scientific community and beyond has affected the scope of research and teaching infrastructure considerably as well. In order to allow a better understanding of these development processes, the present article gives an overview on the most important past and current institutionalized social and behavioral science activities. In doing so, particular focus is put on cross-national research and teaching in the European social science.

Development after 1945

Modern social science, having originated in Europe, emerged as an institutionalized activity in research and teaching only after – and strongly influenced by – its powerful development in the United States. Its evolution in the twentieth century bears the imprint of the authoritarian and totalitarian regimes in continental Europe. While emigrant scholars contributed greatly to the development of the social sciences in the US, the scientific evolution in continental Europe became largely interrupted – more so in Germany and also in Mediterranean countries, and, to a lesser degree in France and Scandinavia. (The summary given in this article follows the "four phases of development in the social sciences" as delineated by Martinotti, 1999: pp. 87–91; for France, Italy, and Germany see also Wagner, 1990.)

By the end of the World War II, the social sciences hardly played any role in the European universities. For example, in sociology, there were only three chairs in France and none in Italy. In West Germany, political science chairs and a disciplinary association did not exist until 1950. To go to the US and study at an American university for sometime, therefore, became an almost necessary precondition for the further education and training of social scientists in Europe. Experiencing 'modern society' and learning the new skills of its systematic observation, made a particular impression on young scholars from countries like Germany, Italy, Spain, and Greece, which had been isolated from modern culture for decades. But it is also true of the Scandinavian countries, where the proximity of the Anglo-Saxon world favored cultural transfer.

As the postwar economic recovery progressed, it became generally understood that the social sciences were part of the modernization of Europe, seen as the expansion of the capitalist mode of production, as well as the democratization of society, both closely linked with the American model. While this caused conflicts and resistance from traditional cultural elites and the Marxist-oriented intelligentsia, there was an increasing diffusion of quantitative methods of data collection, particularly survey and primary data. While it is true to say that the European social science tradition had its own deep experience in quantitative analysis, one must also recognize that empirical research had mainly been based on the secondary analysis of 'process-produced data,' particularly statistical data collected by public authorities. What was missing in the continental tradition, and particularly in those countries that had been under despotic regimes, was the experience of field research and the collection of primary data (Martinotti, 1999: p. 89). Resistance to the introduction of these new instruments, particularly survey methods and sampling techniques, became expressed from different points of view of traditional European scholarship as well as from administrative agencies with their customary statistical procedures.

Under these circumstances, it was not before about 1960 that one can speak of a major expansion of research and acceleration of its academic institutionalization. European societies went through a period of economic 'upswing' that made large masses move to the metropolitan centers of industrial development. The postwar generation of young people, mobilized with the rapid expansion of educational systems, grew up as part of a mass culture, reinforced by the media, that provided a setting for the diffusion of ideas, lifestyles, and new organizational patterns without precedent in the European experience. The social sciences, particularly the younger and newly built-up ones, notably sociology, became highly attractive to the student generation for a number of reasons: the relatively young age of university personnel, compared with more established disciplines; the less precise definition of the academic institutionalization of the social sciences; and the proximity of their subject matter to the intellectual and existential preoccupation of the newly mobilized social groups.

From this background there emerged, in all European countries, a demand for theories of political relevance and of significance for diagnosing and overcoming societal problem constellations (see Dierkes and Wagner, 1992: pp. 612–615). This interest, with its commitment to change, stood in opposition to the program of a supposedly ahistorical and value-free explanation of social phenomena. Intellectual controversies and debates within the disciplines pitted the American social science tradition against a variety of Marxist approaches and

other 'critical' schools with their supposedly more 'enlightened' responses to the demand for a more encompassing understanding and a more 'committed' interpretation of social facts. With this orientation, major streams of the social sciences, with Paris and Frankfurt as major centers, acquired a somewhat militant role, linking up with new social movements and entering into debates about the engagement of intellectuals. The traditional social structures and actors, however, managed to retain their overall influence and to uphold traditional explanations for problems of economic and social change. Social science research in much of the 1960s and 1970s can therefore be characterized, on the one hand, by innovative work in many areas, e.g., political participation, labor organization, class structure, the 'capitalist state,' and problems of personal and sexual relations. On the other hand, theoretical innovation was limited and research perspectives remained concentrated on the nation-state – despite a growing awareness of conflicts posed by North–South differences, the role of multinational corporations, or global environmental problems.

It was in the later part of the 1970s and in the 1980s that the turmoil of debates, the imbalances between issues and approaches, the dividing lines between theoretical and empirical research gradually became superseded by an ongoing process of professionalization, of methodological consciousness, and of new theoretical directions. In retrospect, we can speak of a phase of consolidation in the social sciences in the period of economic recovery after the oil crisis. At a time when liberal social philosophies became dominant, with political sentiments tending to be antiwelfare, and economic policies being influenced by monetarism, the overriding mood seemed to run against the interest in social conditions and the study of society. While this indeed in some countries, notably the UK under Prime Minister Thatcher, made for severe cuts and structural changes, the science policy pendulum did not swing to similar extremes in continental Europe. Debates over the social sciences gradually shifted from theoretical controversies to discussions of their 'uses' in public affairs and policy-making. But by and large institutional growth continued, then slowing down to reach a steady state on advanced levels (see Martinotti, 1999: p. 90, Wagner, 1999: pp. 29, 39).

Toward the end of the 1980s, the social sciences had become well-established academic disciplines, and their presence in policy-making had been well advanced. The academic expansion had very much been related to, and benefited from, expectations with regard to practical uses of the social sciences in the process of societal modernization, which had become an important objective, actively pursued by parts of the political and economic elites. In the process, the role of intellectuals became redefined, turning from persons reflecting in general terms about the fate of humankind in history and society to experts for matters of steering society and the economy, and providing knowledge usable as a tool in reformist policy interventions. After the end of the high expectations about the 'scientification of politics' allegedly leading to the 'end of ideology,' social research had become a routine element of many policy processes and, in the late 1980s, of management in private companies as well (see Wagner, 1990: pp. 441ff). The increasing specialization of the applied social sciences, as well as the general trends of the professionalization of the disciplines and their institutionalization in universities and research centers, brought about an increasing fragmentation and specialization, which has sometimes been related to a tendency of 'deconstructivism' with critical attacks on large theoretical systems and linked to postmodernist movements. But these tendencies more often are understood as part of a more general search for theories capable of combining macrotrends with microsocial and individual dynamics, and, in so doing, aiming at overcoming the traditional juxtaposition of qualitative and quantitative methods, looking for integration in unified research designs (see Martinotti, 1999: p. 90).

Having developed to this advanced stage, the social sciences in the 1990s had to reorient themselves under two dramatic changes of focus: first, the end of the East–West opposition, and second, the process of globalization and internationalization in world regions, particularly the construction of the European entity.

There is an ever more strongly articulated need to gain a better understanding of and to contribute to problem-solving in the process of European integration. Developing a concept of European society has become a major challenge for the social sciences, which have traditionally evolved around the concept of a nation-state and of national societies under the stresses imposed by industrialization. In the last decade of the twentieth century, social scientific research the world over paid special attention to the post-socialist transition, especially in the countries of Central and Eastern Europe (CEE). Only slowly, but with increasing intensity in the first decade of the new century, has it become recognized that the tools and working conditions of social research need to be made adequate for the study of new problem constellations and supranational processes, and that social science policy-making and research programs have to be oriented toward cross-national comparison and international cooperation, particularly on the European level (see Dierkes and Biervert, 1992; Kaase et al., 1997; Erikson, 1999).

National Environments and Institutional Structures

At the beginning of the twenty-first century, it is fair to say that in the European Union (EU), the social sciences have become a standard element in higher education, in public debate and media coverage, in policy-making, administration, and corporate management. While, generally speaking, the knowledge of social reality and the diffusion of social facts have become vastly expanded in the previous five decades, the infrastructural basis for generating this knowledge has developed differently in the individual countries. The disciplinary boundaries of the social sciences, research approaches, problem orientations, and structural differentiations in the build-up of research facilities have become shaped by the respective national environments with their historical preoccupations, their academic-scientific 'cultures,' their political and administrative traditions. Expectations regarding the usefulness of social science knowledge for policy-making and the periodically strong demand for social science expertise have contributed to the institutional consolidation and at times – in varying degrees from country to country – to a push for new research structures reflecting characteristic orientations, problem constellations, and modes

of public discourse (see Wagner et al., 1991; Neidhardt and Smelser, 1992).

For example, the social sciences in Sweden may, to a considerable degree, be characterized by pointing, on the one hand, to a traditional demand for exact and reliable methods, going back to early studies of migration and social movements, and by referring, on the other hand, to the interaction with social policies in the Swedish welfare state model and thus to particular forms of contributing to problem-solving as well as, in the process, refining the theoretical outlook on society.

Contemporary social science orientations may often be explained in terms of specific historical evolutions. In the Netherlands, for example, there had been an early involvement of social science research in the practical problems associated with the territorial aspects of social planning, and the social sciences had become shaped in a continuous development by the specifically Dutch version of political conflict resolution, the *pacificatie*, and the corresponding development of institutional networks for interest mediation. While the forms of policy advisory work and research contracting in the Netherlands can thus be characterized in terms of pragmatism, tolerance, and depoliticization, it is quite a different picture that one would paint for Austria. Here, in the prewar period, the constellations of political conflict did not allow for the continuity of similar pragmatic approaches, and the modes of conflict resolution established after the war led to the involvement of social science approaches in the specifically Austrian type of corporatism, making for quite a different variant of a more general continental European phenomenon: the integration of social science research in institutional structures of political representation and in channels of communication between politics, public opinion, policy-making, and scientific expertise (see Wagner, 1990: pp. 460–463).

These examples, while meant to underline the importance of the diverse national settings, may also serve to illustrate a more general thesis explaining social science orientations with reference to historical paths of social and political development. In these terms, the social sciences emerged in Western European countries in a markedly different way from the way they evolved in England and the US, where the continuity of individualism and civil society made for a more pragmatic style of studying social and political problems empirically and with reformist perspectives. The social sciences on the European Continent, in turn, have been characterized by addressing more basically the foundations of a social and political order, which – given the traditional social conflicts, ideological cleavages, and propensities for radical change in Europe – have time and again been called into question. They have also shown a greater tendency to ascertain their basic categories and critically discuss their knowledge base.

Institutionally, in all European countries, the major part of social science research takes place within the university system. This refers first – and for most countries, foremost – to a multitude of small production units attached to professorial chairs in university departments and loosely organized faculties. Depending on the relative number of students and the weight of the professorial teaching load, university research consists mainly of small projects done with students and often linked to their theses.

At many universities we find, under similar names, institutes for social science research as organizational entities meant to provide better opportunities for cross-disciplinary orientation, for cooperating in empirical research and for contracting and administering larger projects with outside funding. But it is only at very few places that such additional forms of institutionalization, in combination with a considerable number of professorial and other staff positions in the respective departments, have led to larger and more consolidated university research centers. In Germany, such larger agglomerations of the social sciences exist at the universities of Mannheim, Cologne, Bielefeld, Berlin, and Munich (see Neidhardt, 1999).

By and large, however, it is outside the universities that more extensive research structures have become institutionalized. Extra-university institutes form a second element in the 'academic research system' in as much as they are to some degree publicly funded and not dependent in their agenda setting on short-term opportunities offered by the markets of policy analysis and corporate consulting, but rather able to integrate individual projects into larger programs. While indeed at times working on research tasks aimed at contributing to problem-solving, such establishments usually understand themselves as knowledge-oriented and 'science-driven,' and are – at different levels – connected to the universities (see Wagner, 1990: p. 441ff).

These institutes vary from country to country in number, size, and concept, depending on the respective national environment. In some cases, there is only one such extra-university institute as a central establishment, like the Greek National Centre for Social Science Research in Athens. The German case demonstrates a functional differentiation in two directions, which, for structural reasons, did not easily develop within the universities and thus called for extra-university institutionalization: on the one hand, the *Wissenschaftszentrum Berlin für Sozialforschung* (*WZB* – Social Science Research Centre, Berlin) and some institutes of the *Max-Planck-Gesellschaft* and of the *Leibniz-Gemeinschaft* (*WGL*), which undertake larger, long-term, internationally comparative, or problem-oriented projects in transdisciplinary research groups; on the other hand *GESIS-Leibniz-Institute for the Social Sciences*, a group of social science infrastructure establishments in Mannheim, Cologne, and Bonn, which provide professional services in support of social science research by documenting research projects and their results, by advising researchers on project design, by offering courses in advanced methodologies, and by archiving and giving access to empirical data for the purpose of secondary analysis.

Compared with the grand total of resources and activities in the universities, the 'extra-university' sector of the academic research system is still rather small in Germany and even smaller in Italy with only a few institutions of the *Consiglio Nazionale delle Ricerche* (*CNR* – National Research Council). In France, however, this sector is considerably larger, due to the historic separation of the universities from the centers of academic research. The dominant institution is the *Centre National de la Recherche Scientifique* (*CNRS*), which runs a large number of research institutes separately from or in cooperation with universities or *grandes écoles*; for sociology and ethnology, the *CNRS* with its division on the *Sciences de l'Homme et de la Societe* is far more important as a research institution than the

universities. Furthermore, there are the *Maison des Sciences de l'Homme* (*MSH*), the *Ecole des Hautes Etudes en Sciences Sociales* (*EHESS*), the *Fondation Nationale des Sciences Politiques*, the social science sections of the Paris Museums, and the *Collège de France* (see Machin in Lisle et al., 1984).

The basic institutional setup of the academic research system is – in varying forms of composition – being supported and complemented by a third institutional element: the system of project funding through national organizations and foundations. To take the German example again, the *Deutsche Forschungsgemeinschaft* (*DFG*), a publicly funded association of institutions of higher education and research, provides good opportunities for good projects – in whatever kind of research design – to be financed, supplementing the existing institutional resources and using peer review procedures to evaluate project applications. Moreover, the *DFG* and, with greater emphasis, other funding organizations (like the *Volkswagen Stiftung*) make attempts to establish researcher networks and cooperative arrangements within larger, more integrated research programs.

In addition to these institutes and programs that are constituted on scientific grounds with a primary interest in knowledge generation, we find in all the Western European countries other types of social science institutions that are – again in different forms and in varying degrees of development – oriented toward practical needs of government agencies and private organizations. These are, first, publicly financed research institutions directly operated by the state and subject to directives from the respective ministry interested in having a particular need covered by research and analysis. As a second type there are privately organized institutes, which may have some basic institutional budget, but receive the main part of their resources from contracts for work on projects commissioned by government agencies as well as corporations, unions, the media, etc. The 'state-administrative' part of this sector, often with longer traditions, comprises statistical and agronomic analyses, research on land use and regional development, on demography, public health, on education and vocational training, etc., usually with a strong empirical quantitative orientation. Such 'contractual' research became more developed in the 1960s and 1970s, relating to the policy issues of the day, and sometimes developing a marked expertise through repeated studies over time in a given area.

In some nations and at certain periods in their development, this sector may gain considerable – even dominating – weight in the overall spectrum of social science research (see Wagner, 1990: pp. 443–447). In the context of this article, however, there is no room for elaborating, e.g., on the importance of the government-directed nonacademic research sector in France, on the effects of administrative traditions and statistical-quantitative orientations, or on the channels for linking social science research to the system of 'planification' through, for example, the *Comite d'Organisation des Recherches Appliquées sur le Développement Economique et Social* (*CORDES*).

These different forms of applied research are indeed part of the institutional environment and the operating modes of social science research in the respective national contexts. However, while they provide career paths for social scientists and demonstrate the public use of social science knowledge, their infrastructural functions remain rather restricted in comparison with the academic research system with its opportunities for research experiences in larger contexts, for methodological training, for internationally comparative ventures, and for exchanges between approaches and orientations.

Strengthening the European Research Base

Social science research in Europe, in summary, has become institutionalized in a variety of national settings and organizational structures, depending on each country's specific historical background and cultural contexts. International exchange and cooperation, first with the United States, then increasingly across Europe, have served to develop the social sciences to higher degrees of professionalization, with a growing interest in cross-national comparison, but have by far not yet come near to what might be called a 'European' social science. At the beginning of the twenty-first century, the ongoing process of European integration had still not become adequately developed as a subject of research aiming at understanding the preconditions, the conduct, and the consequences of this process. In addition, the EU itself, its institutions and major policy areas require the increasing attention of the economic and social sciences, and it has become a matter of 'social science policy' concern to evaluate and redirect the structural conditions of social science research in the European countries and the perspectives of its development 'toward Europe.'

At the outset of such assessments, it has widely become recognized that the fragmentation of the European systems – in terms of social, political, and economic problems as well as science and research structures – should not only be understood as obstacle and retardation on the path to a truly European outlook. Turning disadvantage to benefit, one can see European social sciences, with their subject matter differing to some extent from country to country, as providing a densely developed empirical basis for generalizations across time and space. With its richness of constitutional, institutional, and cultural variations across (and also within) nation-states, Europe has come to be interpreted as a 'natural laboratory' for the social sciences, leading to strong recommendations concerning systematic empirical comparative research (see Kaase et al., 1997: pp. 3–4).

While the social science infrastructures in the different European countries have so far been mainly directed toward the study of national developments and problem-solving dimensions, the past decades, with still limited success, have put forward the notion of an increasing need for international cooperation and the corresponding infrastructures that make for exchanges, collaborative work, and joint projects. Network linkage has been advanced through the establishment of European journals in different disciplines, through a 'Network Scheme' by the *European Science Foundation* (*ESF*) and through European networks of research units. The most successful of these has been the European *Consortium of Political Research* (*ECPR*) with currently around 400 European institutional members and associate members in over 50 countries, from as far afield as New Zealand and Japan. The *ECPR* organizes annual joint sessions of workshops, which take place in

different countries and bring together about 500 European political scientists. A similar organization, the *European Consortium for Sociological Research*, exists for the neighboring discipline.

Meeting grounds for groups of researchers from different countries and opportunities for collaboration on joint projects over a period of time are being offered by institutes of advanced study, particularly the *Netherlands Institute for Advanced Study in the Humanities and Social Sciences* in Wassenaar and the *Swedish Collegium for Advanced Study in the Social*.

Sciences in Uppsala as well as – with a more general orientation reaching beyond the social sciences – the *Wissenschaftskolleg zu Berlin* or the *Central European University's Institute for Advanced Study (CEU IAS) (earlier under the umbrella of the Collegium Budapest, Institute for Advanced Study, whose operation has to be terminated in 2011 lacking of sufficient funding*). The latter, together with other centers of excellence in CEE countries, is meant to advance research capacities within its region by, not least, providing links with researchers from Western countries.

In the Framework Programmes (FP) of the EU the social sciences have not, until the 1990s, played an explicit role other than having been eligible for the funding of networks of younger researchers as part of general 'Human Capital and Mobility' or 'Training and Mobility of Researchers' programs. The Fourth FP (1994–98) did for the first time contains a separate program relating to the social sciences, 'Targeted Socio-Economic Research.' One part aimed at the evaluation of science and technology policy options in Europe. It included a part on research on education and training and one on research into social integration and social exclusion in Europe. The latter addressed processes of social exclusion and integration, causes of social exclusion, particularly unemployment, the impact of social integration policies, and research infrastructures. (For the EU research programs see http://cordis.europa.eu/home_en.html.)

The EU Fifth FP (1999–2003) contains, as a major instrument, 'Key Action: Improving the Socio-Economic Knowledge Base,' directed at research tasks on the management of societal change, on individual and collective strategies in a changing society, on employment and unemployment and on social cohesion in Europe, on new perspectives for learning, on governance, citizenship, and the dynamics of European integration, and on the challenge of EU enlargement. Under the Sixth FP (2002–06), this type of research found a place in the 'Citizens and Governance in a Knowledge-based Society' Programme. It mainly focused on both improving the generation, distribution, and use of knowledge and its impact on economic and social development, and identifying implications of European integration and enlargement for governance and the citizen. In the current programme, 'Socio-economic sciences and the humanities' (SSH), which is part of the European Research FP7 (2007–13), emphasis is given to eight areas, all of them aiming to study and offer answers to questions regarding the demographic change and quality of life; education and employment in view of the current economic trends; global interdependence and the transfer of knowledge; the well-being of democracies and political participation; cultural diversity and the values. (More details to the SSH as part of the FP7 see at http://cordis.europa.eu/fp7/ssh/about-ssh_en.html.)

In addition, the interest in social science research has become expressed in an ongoing increase of the budget available for social science. As a case in point, whereas the above mentioned SSH had a budget of € 610 million available of a total budget of around € 50 500 million (12%), a budget of € 29 700 million, 37% of the total € 80 000 million, is currently foreseen for research in societal challenges under the EU program Horizon 2020. This is an increase of nearly 25% in real terms compared with its predecessor, the FP7.

For the researchers, participation in the European research programs has meant, depending on the background of their experiences in the respective national systems of research funding, a reorientation toward new requirements and procedures, sometimes deviating considerably from established modes of competitive research application and evaluation. Following critical discussions and corresponding adjustments of program definition, of evaluation criteria and financing mechanisms, criticism, partly even opposition, centered on the bureaucratic procedures, on the professional status and the scientific excellence brought to bear on program design and project assessment, and on the policy orientation of EU research. (For a general discussion of EU research structures and policies see Max-Planck-Gesellschaft, 1994.) It remains to be seen whether the social science research task in the seventh and in subsequent EU FP such as the Horizon 2020 will reflect a convergence between competing principles and complementarity between the research programs of the EU, on the one hand, and the ESF with the different national research councils and scientific organizations, on the other.

One item of discussion that may lead to a clarification of perspectives and differentiation of roles is the desirable balance between basic and applied research in response to the 'European' dimensions of EU research tasks and their relatedness to EU policy areas. (As a position in the discussion, calling for more basic research, see Erikson, 1999: p. 32.) One example is the expression of the overall objective of the program, 'Improving the Socio-economic Knowledge Base' Key Action, namely:

> to make best use not only of the solid base of social science research that Europe has at its disposal, but also to harvest Europe's immense cultural diversity. It aims to improve our understanding of the structural changes that are taking place in European society, so that we can manage and direct the changes and involve Europe's citizens more in shaping their own futures. The Key Action will allow the results of various different types of work – empirical, comparative and prospective research – to be brought together within a cohesive framework. It will therefore be in a position to provide policy-makers with a sound knowledge of the challenges facing Europe, and of the policy options that are open to tackle them. It will focus on four areas.
>
> European Commission Publications; see http://ec.europa.eu/research/improving/leaflets/en/keyact01.html

Under this general headline, there has been a pronounced emphasis on four areas: (1) societal trends and structural changes, (2) technology, society, and employment, (3) governance and citizenship, and (4) new development models. The first will aim to clarify structural changes and other complex interactions between societal trends, changing lifestyles, economic evolution, labor market institutions, and cultural

patterns. The second will investigate the way different types of institutions – businesses, schools and universities, local authorities, governments, and consumers – interact to invent, produce, and market innovative goods and services. In addition, the area of the governance and citizenship aims to research the role that the various levels of governance (local, regional, national, and EU) play in Europe, and look at ways in which their interaction and accountability can be improved. Finally, the last area of the Key Action, the new development models, will investigate the dynamics of wealth creation and distribution in a global economy where intangible factors predominate. It will explore new sustainable development models that will square the circle by simultaneously fostering growth, job creation, environmental protection, equal opportunities, the reduction of inequalities, and improvement of the quality of life. (European Commission Publications; see http://ec.europa.eu/research/improving/leaflets/en/keyact01.html.)

The interest in 'Data integration' and 'research infrastructure' has become a common effort in other policy measures as well. It suffices to mention Eurostat, the statistical office of the EU. Even though it was originally established to meet the requirements of the Coal and Steel Community, over the years it has increasingly included social sciences in EU actions to support 'large-scale facilities' and by promoting 'access to infrastructures,' widening the notion of infrastructures from establishments for data processing and archiving to functions of opening up particular research experiences by coordinated international exchanges. Currently, its task has broadened to collect data for Economic and Monetary Union and developing statistical systems in candidate countries for EU membership so they can define, implement, and analyze Community policies more effectively (see Changing Role of Eurostat at their Web sites www.eurostat.ec.europa.eu).

This interest meets with a core concern of the ESF, particularly its Standing Committee for the Social Sciences, which has been active, albeit with limited resources, not only in promoting thematic projects in international cooperation, but also in the discussion and recommendation of social science policies and infrastructural development. In this context, it has prepared the proposal for a 'European Social Survey' which in a number of respect overlaps with, or runs parallel to projects partly financed by the European Commission, to develop a 'European System of Social Reporting and Welfare Measurement,' with about 20 national teams, including some Eastern European countries.

With the efforts to create a 'European System of Social Indicators,' emphasizing the scientific context and research dimensions of social reporting going beyond 'mere statistics,' an early interest of the European Community of the 1970s is being taken up again, very much in line with the corresponding activities of the Organization for Economic Co-operation and development (OECD), following the strong signal given by the so-called Brooks report on 'Science, Growth, and Society' of 1971 with its explicit inclusion of social science research in science policy concepts. In a report of 1997 for the *European Science and Technology Assembly*, an advisory body to the EU, a panel of leading social scientists completed a survey of the strengths, gaps, and weaknesses of the economic and social sciences in Europe. In this, they recommended measures for the support and advancement of interdisciplinarity for problem-driven research, particularly flexible organizational modes to link scholars from different, even distant, disciplines for a limited period of time; the comparability of data, especially longitudinal microdata, and the systematic linkages necessary for multilevel analyses; the research training of young scientists through graduate colleges, summer schools, etc.; incentives for independent work at earlier stages in academic careers; networks between funding organizations for granting money to comparative projects; national concentrations of methodological resources (similar to *ZUMA, the Zentrum für Umfragen, Methoden und Analysen*, in Mannheim) and links between them across Europe (see Kaase et al., 1997: pp. 4–10). The need for developing a common European research and training agenda was also pronounced by Federico Mayor, the former Director General of UNESCO, following a series of conferences concentrated on European perspectives on the social sciences (see Mayor, 1998).

These efforts from both the UNESCO and EU, together with the process of EU integration and EU enlargement, inter alia, have obviously stimulated the development of social research activities. A growing emphasis has been put on empirical data collection and analysis in recent years (see, e.g., European Commission, EU social indicators) aiming to monitor and systematically describe, inter alia, the current state of and changes in living conditions and the quality of life – not only at the supranational, but also at national and subnational level in all old and new Member States (see Noll, 2002: p. 2). Such developments can be regarded as fruitful in a wider sense: not only do they help to comparatively understand social, political, and economic structures in national contexts; but they also call for studies of intersocietal penetration and of arrangements that work toward international cooperation and integration between the EU members.

In addition to the increasing importance of cross-national research activities in the European social science, the teaching infrastructure in the EU has been also continuously extended at an international level. As a case in point, the European Commission has been increasingly put on emphasis on financial support of actions in the fields of Education (Erasmus, Leonardo da Vinci, Comenius, and Grundtvig), international Training (Erasmus Mundus, Tempus, Alfa, Edulink, the programme for cooperation with industrialized countries), Youth (the Youth in Action programme), and Sport (the new sport action). Finally, the latest EU Programme, Erasmus+ (2014–20), aims to bring all these seven programmes together. The programme gives opportunities to students, trainees, staff, and volunteers to spend a period abroad to increase their skills and employability. It supports organizations to work in transnational partnership and to share innovative practices in the fields of education, training, and youth. By increasing mobility between the EU and the Third Countries, in accordance with EU external policy objectives, it also contributes to the development of human resources and the international cooperation capacity of Higher education institutions in these countries (see European Commission 'Erasmus + 2014–20 Programme Guide').

In general, it can be stated that the EU has strengthened to some extent the role of social science within its borders. A pluralist and transnational social science in Europe should, however, keep looking for closer relations with social sciences in Asia, Africa, and Latin America, in addition to its profound ties with North America, in order to address and bring forward the need to link to global-wide concerns.

Social Science Learned Societies and Professional Associations

Abstract

The historical emergence of social science associations, as part of the academic institutionalization of the social sciences, is sketched, and the membership and typical functions of learned societies – in particular their conferences, journals, and research sections – are described. The pattern of affiliations between disciplinary and cross-disciplinary, and national and international, associations is outlined, and it is suggested that these are sufficiently structured and comprehensive to have created what is in effect a world system.

What do we count as a social science association? In this context, it must be an organized body which figures in academic social science. However, the history of such bodies shows that some formal organizations have started much less formally, that the boundaries between academic and nonacademic have changed over time, that 'social science' may be more concerned with practical reform and social interventions than with social theory, and that some bodies straddle boundaries between social and physical science, or between social science and history or literature. The situation must be drawn more broadly to show the full picture.

The range of relevant associations has expanded enormously, starting with their development in the second half of the nineteenth century; before then, the main predecessors were on the one hand 'academies', usually autonomous national bodies representing wide fields of science and learning and with a socially elite membership, or informal 'invisible colleges', or on the other hand bodies concerned with social reform, such as the American Social Science Association (founded 1865). (Alter (1980) describes the emergence of an International Association of Academies, a German scientific initiative, and shows how what presented itself as learned collaboration transcending national boundaries was inevitably entangled with major political and economic changes and conceptions of the national interest.) There are different types of association, their difference traditionally labeled in English as that between the 'learned society', which concentrates on the advancement of the intellectual content of its sphere, and the 'professional association', largely concerned with the more material occupational interests of its members. The 'qualifying association', whose functions include the award and policing of the conditions of a qualification necessary to practitioners, could be seen as bridging that gap. Existing associations are certainly not all pure examples of these types, which should be treated as abstract concepts rather than empirical descriptions. This article focuses on the learned society bodies and functions.

Functions

Learned societies perform a wide range of functions. These commonly include the holding of conferences at which papers are given, the production of academic journals, and the representation of their constituency's knowledge and interests to the educational system, government, and the wider public; they may also include the award of prizes, the provision of training activities, the sponsorship of research, the production of teaching materials, the creation of sections for members working in specialized topic areas, and the establishment of ethical codes to guide professional behavior. Described in more theorized terms, these functions include establishment of the legitimacy of their field's knowledge claims, knowledge transfer, the maintenance of intellectual standards, disciplinary socialization and social control, and the encouragement of intellectual cooperation and social integration among their members. There is considerable variation among existing associations, depending on their size, history, and local traditions, but with a tendency for the same patterns of activity to diffuse across the field, even if similar functions are performed in different institutional ways. The larger associations have the resources to perform multiple functions.

Membership

Association members may be individuals or groups. Individual membership has more often in the past been confined to elite categories such as university professors, or holders of doctorates, and is still sometimes honorific and by invitation only, but in recent times the admission on application of at least other members of university faculty and of students has become normal. Where group membership exists it is commonly defined by discipline in cross-disciplinary national associations, and by national disciplinary association in international associations; the latter has been the standard pattern within the United Nations Educational, Scientific and Cultural Organization (UNESCO) sphere of institution-building (see later), though as the numbers of social scientists have grown the importance of individual membership alongside national representation has expanded considerably. Within this basic framework, room has often been found for cases which do not precisely correspond to the original constitution's concept. Thus, there is sometimes special provision for social scientists working outside academia, or for representation of teachers of a discipline in schools, whether within the structure of the national association or by the affiliation to it of a specialist association. Social scientists from the academic world's periphery (however, that is defined) often find reason to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03006-3

establish some affiliation with its perceived center, promoting social integration of the disciplines.

The System of Associations

An important contribution was made to the emergent pattern of associations by the policy of UNESCO which, following on from the pre-war League of Nations Committee on Intellectual Cooperation, in 1948 started to develop a plan to bring national bodies together and promote internationalism in the interests of world peace; it was hoped that cross-disciplinary and cross-national research would support that. Sometimes an earlier international association already existed that could be used as a basis; the formation of national associations to fill gaps, and affiliation to international bodies by those that already existed, was actively encouraged. (In the case of sociology, however, leading members of the Institut International de Sociologie (IIS) were felt to have been sufficiently close to fascist regimes for that to be unacceptable, so the foundation of the International Sociological Association (ISA) was set in motion (Platt, 1998: pp. 27–28).) An organizational hierarchy has thus in effect been created by UNESCO, making use of existing developments, in which national disciplinary associations are gathered together into international disciplinary associations, and those in turn are the members of cross-disciplinary associations such as the International Social Science Council (ISSC) and the International Council for Science (ICSU). (The latter retains the acronym from when it was known as the International Council of Scientific Unions.) These bodies have not exercised authority over their members, though their access to funds sometimes gives them influence, so they are at the top of the UNESCO hierarchy only in the sense that in principle they include all relevant associations, and their remit is at the highest level of geographical and intellectual generality. This hierarchy ignores the many independent special-interest smaller associations for subfields such as medical anthropology, history of economic thought, biographical methods, or figurational sociology. These are important, but in their intellectual activities very similar to sections, sometimes moving between or combining section and independent status, so are not discussed separately here. In this article, we start at the bottom of the hierarchy.

National Disciplinary Associations

The process of formation of national disciplinary associations is part of the establishment of a discipline as such, and of its professionalization. (The members of a national association are not necessarily citizens of that nation or working in it. For instance, in Britain 60% of individual members of the Royal Economic Society are recorded as living outside the UK; that is probably an extreme case (http://www.res.org.uk/view/index.html).) In many countries, there were no such associations by the 1950s – indeed little or no academic social science, though there might be more or less formal groups of intellectual notables, and what is now recognized as social science in contexts not given that name. National disciplinary associations are voluntary associations, not state bodies; they normally have elected officers serving fixed terms, often supported by an office staff, although much essential work is also done by post-holders without payment. In those countries which had developed some academic social science by then, mostly in Europe and North America, the process leading up to the modern situation started around the mid-nineteenth century. When the push to create national members for international associations came in the 1950s, many more emerged. Henderson (1996) gives detailed accounts of the emergence of German and British national economic associations, while Fourcade (2009) places French, British, and US economics associations in broader national contexts; Celebi (2002), Glatzer (1994), Patel (2002), and Platt (2003) deal with sociology in Turkey, Germany, India, and Britain. These examples are sufficient to indicate the diversity of the routes that may be followed, and the extent to which they may depend on current political concerns and the existing structure of associations – but still reach similar goals. Such bodies surely offer the commonest form of social scientific associational participation.

In countries with relatively small numbers of social scientists, whether as an effect of small total population size or the early stage of disciplinary development, ways have been found of creating viable associations based on larger constituencies. Thus in Canada for some time there was one national association for both anthropology and sociology, while in the antipodes there was a joint Australia/New Zealand sociological association (Crothers, 2005: pp. 73–75); both have now divided. In addition to such bodies, both the British Association (whose section on anthropology, for instance, started in 1884) and the American Association for the Advancement of Science were bodies, facing toward a broader general public, which covered a broad range of disciplines, including social sciences before there were single-discipline national associations. Larger regional associations such as CODESRIA (Council for the Development of Social Science Research in Africa) have been accepted by the international bodies into the same category as national members, and can offer more locally shared solidarity and frameworks of reference, as well as some international perspective, at lower cost. Cross-disciplinary national associations are less common; their appearance may be the start of the emergence of a new discipline. But when government policy affects broad areas of academia there have been cases, such as the USA's Consortium of Social Science Associations (COSSA), where associations have united in a new national body to defend their shared interests. Similarly, groups such as Sociologists for Women in Society cut across disciplinary boundaries as they address both the position of women in academia and the need for gender to be taken into account in its intellectual products.

There are also cases where national subdivisions, such as the English/French language cleavage in Canada, are important enough to lead to separate associations. Patel (2002) sees the Indian academic community as sharply hierarchical, with an important division between universities teaching in English and in local languages; the national association is mainly for the former group, while the latter have established a number of local associations. The USA used to have a Catholic association, now defunct, and the originally oppositional Society for the Study of Social Problems continues (while the American Sociological Association remains clearly dominant), but the country also has thriving regional groups such as the Southern

Sociological Association (Simpson, 1988: pp. 1–17) which provide contacts closer to home geographically.

International Disciplinary Associations

The main international disciplinary associations are in principle world-wide, although in practice the uneven diffusion of social science sets limits to their constituencies. Local differences in intellectual patterns contribute to the observed differences in the dates at which national associations have affiliated to the international associations of different disciplines, but each now has a very large number of national affiliates. (The total number of collective members available is subject to political events; thus the dissolution of the USSR increased the number markedly, while the reunification of Germany and division of Czechoslovakia halved and doubled their representation.) The collective members of these associations include some regional associations for Europe, Africa, and the Asia–Pacific area.

There have sometimes been frictions over the patterns of representation. The IIS for a while competed with the ISA to be regarded as the world association, organizing parallel world congresses, but eventually peace was made and IIS became formally affiliated to ISA. Although the headquarters of UNESCO were in Paris, and French was one of the ISA's official languages, US hegemony made English more salient; when the proposal of a French-speaking ISA section was rejected a separate francophone association, the Association Internationale des Sociologues de Langue Française was founded in 1958. That continues successfully to this day, but has also long made peace with ISA and become affiliated. A similar accommodation was reached between the International Union of Psychological Science (IUPsyS) (which also has a francophone affiliate) and the earlier International Association of Applied Psychology (IAAP); IAAP is now affiliated to IUPsyS, and their conferences alternate. By 2000 IUPsyS also had nine other affiliates, some of them regional groups (Rosenzweig et al., 2000: pp. 2–3).

One of the major problems that the international associations face is how to get sufficient funding to support a desirable range of activities; membership subscriptions are paid, but to make the essential membership from the global South (and students) practicable charges to them have to be low, and there may not be much practical scope for subsidising them from the North. Most associations may draw on a considerable input of voluntary labor, but that has its limits, and is particularly poorly suited to running a central office. The modern solution is to budget for profits from conferences and journals. The possible effects of the 'open access' movement on journal profits will only be seen in the longer term.

Sections

Disciplinary associations both national and international usually have 'sections' defined by their specialized research interests; how many are generated is influenced by the size of the membership, but there appear to be both some generally shared concerns, some of them responding to wide social movements such as feminism (Platt, 2010: pp. 109–110), and specifically national ones such as the Indian Sociological Association's 'Dalits and Backward Classes' or the Deutsche Gesellschaft für Soziologie's 'Ost- und Ostmittel-europa-Soziologie' (the latter now renamed 'Europasoziologie') which have arisen from local situations. (Some in practice are not confined to members of the discipline; lawyers appear in sections on deviance, clergy on religion, nurses on health and medicine.) Their size may vary considerably, which affects their programs, but a minimum level of activity is to organize meetings at world congresses and to circulate a newsletter; some will have more meetings, take part in joint and comparative research, and publish their own journal. For many individual members, sections have been their main locus of identification within the wider discipline, and the intellectual history of disciplines can in important ways be plotted through study of these groups.

Conferences

Organized international meetings of people with shared interests have commonly preceded the creation of international associations. For instance, international congresses of statistics were held regularly from 1853 to 1876 (Brian, 1989: p. 201); various Congresses of Anthropological Sciences were held before 1865 (International Union of Anthropological and Ethnological Sciences (IUAES) web site); the first of a series of geographical congresses was held in Antwerp in 1871 (International Geographical Union (IGU) website); and a one-off political science congress was held in Paris in 1900 (Coakley and Trent, 2000: p. 11). Thus some conferences led to the creation of associations, rather than being initially organized by them.

The organization of conferences is now a major and regular associational activity, and they have grown in size and expanded in the range of activities they offer. (Tourist offices send representatives to committee meetings to advertise their country's attractions, and firms exist whose business is to organize conferences for associations.) Plenary sessions are held, but the typical timetable of large conferences now provides many points at which choices between speakers, often classified by section, have to be made; special activities for students, or for tuition in the latest developments for faculty, are arranged; large publishers' exhibitions are included, there may be formal space for the conduct of job interviews, and a variety of committee meetings, social scientific tours, and social events are held. There is the opportunity to see the great in the flesh, get comments on your draft paper, develop cooperative work, meet old friends and new ideas, buy cut-price books, learn more about the country where the meeting is held, and maybe add an exotic holiday. Conferences may also serve broader social goals: they were important in the diffusion of early second-wave feminism, and have provided moral support and intellectual opportunities to members from countries where social science is restricted or discouraged.

Meanwhile, it is a recognized problem that many academics can get high costs of conference attendance paid by their department, but only if they are giving a paper; this leads to pressure to accept a large number of papers, so that the timetable becomes excessively crowded and running expenses rise. (Canada has an unusual solution to problems of distance: every year in May/June, a large number of learned societies in the humanities and social sciences hold their annual

conference in the same place and over the same period, maximizing contact possibilities and minimizing travel costs.)

Journals

A major contribution to the literature is made by the journals which associations produce. Crothers (2007) found that 51% of sociological journals listed in the ISI's Journal Citation Reports for 2006 were sponsored by associations; figures for other disciplines are not available, but may well be comparable. Many of these are run by commercial publishers on their behalf (Singleton, 1981), though the associations maintain control over decisions about intellectual content. The possession of an official journal is seen as important to the definition of associational identity (Hudson and Hudson, 2005); national associations normally have one, and may have several, while specialist networks have specialist journals. Long ago now, Lengyel (1967) reviewed the pattern of social science periodicals in the world. He found that different countries had different modes of journal sponsorship, depending on the structure of local institutions; correspondingly, the growth of international journals was related to the rise of international organizations. It is commonly assumed that the national association journals, in particular those with a nonspecialist remit, are at the top of the hierarchy of local intellectual prestige, and can be taken as representing the discipline. Whitley (1970: p. 255) suggests that "The study of journal operation is the study of the application of discipline norms to the judgment of research", and Vanderstraeten (2010: p. 561) sees journals as revealing "the collective character of the scientific practice". Coats' (1971: p. 32) finding that over the period 1886–1959 five general economics journals became increasingly similar in their contents could support this. In that sense, journals and learned societies are inextricably involved with each other as parts of the system of research and disciplinary reproduction.

International Cross-Disciplinary Associations

UNESCO has cross-disciplinary associations for natural science (ICSU), social science (ISSC), and the humanities (ICPHS) whose standard members are international disciplinary associations. Not every existing organization fits neatly into the preconceived categories of the system, but ways have usually been found to incorporate them. The question of where an association belongs has sometimes been answered by its having a dual affiliation; thus both IUPsyS and the International Geographical Union (IGU) are members of both ISSC and ICSU, and the IUAES also belongs to UNESCO's International Council for Philosophy and Humanistic Studies. Some associations involved in the system are not purely or mainly academic. Thus the World Federation for Mental Health, which belongs to the ISSC, has been a movement to promote mental health as much as to study it. Brody (1998: p. 165) notes that since it was not, like other affiliates, composed of academic researchers, it was less easy for it to follow ISSC initiatives up; although it took part in work such as that on human rights and new bio-technologies, it remained an association whose more significant contacts were elsewhere. Somewhat analogous is the International Peace Research Association, founded in 1964. Its main aim is to increase and improve research focused on world peace. Most of its members are not national or regional bodies, but individuals or research institutes. It has worked on topics such as international human rights, and gender and peace, which relate to UNESCO and ISSC agendas, but has not been prominent in ISSC affairs. Thus disciplinary patriotism has not prevented the growth of complex links, perhaps occasionally open to interpretation as disciplinary imperialism. Many ISSC activities have been on a project basis, and it has promoted research on specific topics seen as relevant to its international and cross-disciplinary remit; in recent years there have been major programs of work on poverty, global environmental issues, gender, and disaster risk. It also has responsibility for the *World Social Science Report*, and the biennial World Social Science Forum, a major conference on a topical theme related to ISSC interests.

The ISSC has changed considerably over time, in ways too complex to describe here (but see Platt, 2002). These changes reflect the intersection of the internal politics and policy goals of UNESCO, the funding sources available at different times, the agendas of some charismatic and interested individual social scientists, and the concerns of the growing set of associations involved. Its aim remains to advance the social sciences while attempting to solve global social problems.

Conclusion

The complicated pattern of associations that has developed uses a number of dimensions of classification:

National/regional/international
Disciplinary/cross-disciplinary/sub-disciplinary/topic-specific
Individual membership/group membership
Open individual membership/qualifications for admission/elite selection

These appear in different combinations. It is evident that complex needs are met, and there is considerable practical flexibility to allow new actors to be introduced and interrelationships to be created and maintained. As the social scientific population has increased, its members individual and collective have become increasingly differentiated and specialized, while at the same time arrangements to bring them together in various combinations have evolved. The result can reasonably be regarded as a system of interdependent parts.

Social Science Professions and Professionalization

Felice J Levine and Nathan E Bell, American Educational Research Association, Washington, DC, USA

Abstract

This article focuses on social science professions in the United States. It addresses the nature of these professions, the process of professionalization, degree production and graduate enrollment in social sciences fields, degree completion, and time-to-degree. Moreover, this article examines diversity and the social sciences doctoral degree, international comparisons in social sciences doctoral degree production, and the contours of the labor force in these fields.

Introduction to Social Science Professions and Professionalization

This article focuses on social science professions in the United States. It addresses the nature of these professions, the process of professionalization, patterns of enrollment and degree production, and the contours of the labor force in these fields. Professionalization refers to the processes through which individuals become professionals. Labor force refers to that portion of the population (in this case of social science professions) that is economically active, meaning either employed or, if unemployed, available to work. Although social science professionals are employed across work sectors, special attention is paid to the social science professoriate.

The Social Sciences as Disciplines and Professions

The social sciences refer to a large number of disciplines and interdisciplinary fields that in their own right constitute more than a single profession.[1] Disciplines like economics, political science, psychology, and sociology have their own specialized training, expertise, reward structures, associations, networks, and norms that reinforce distinctive professional identities. As scientific fields dedicated to the study of human social phenomena, they share common features. Yet, because of their arenas of expert knowledge, occupational cultures, collegial interactions, labor markets, and their distinctive identities as perceived by others, they comprise different professional groups. Moreover, these professions are not the same as the academic profession, although many persons with advanced social science degrees (especially with doctoral degrees) are academic professionals at universities and colleges.

The Process of Professionalization

What Is Professionalization

Professionalization involves the development of skills, identities, norms, and values associated with becoming part of a professional group. Through this process, individuals pursuing careers in specific social sciences acquire both substantive and methodological knowledge and develop understandings of their roles that permit them to function as professionals in their fields. By training new entrants and fostering social cohesion and identity, these professions seek to ensure that the work of their sciences will continue congruent with certain core principles and practices. Professionalization can commence during undergraduate education, is central to graduate training, and continues during early career stages.

Research on Social Science Professionalization

Research on professionalization dates back to the 1950s. Early research on professionalization focused on the medical (e.g., Becker et al., 1961; Merton et al., 1957) and legal (e.g., Lortie, 1959; Warkov and Zelan, 1965) professions. At the same time, there was also attention to higher education professionals, with initial research focused on faculty (e.g., Caplow and McGee, 1958; Parsons and Platt, 1968) rather than on socialization to academic or scientific professions (an exception is Berelson's study of graduate education published in 1960).

In the more than 50 years since, an important body of research and scholarship has evolved on the socialization to academic and scientific careers.[2] Much of this work focuses on graduate departments as the primary socialization site in the vital transition from student to professional (e.g., Austin, 2002; Gardner and Mendoza, 2010; Morrison et al., 2011; Weidman and Stein, 2003). In graduate departments, students learn what is expected and rewarded and, conversely, what constitutes unacceptable practices in their field or discipline. Graduate education aims to develop in students a level of scholarly proficiency through formal (e.g., courses, qualifying exams, dissertations and informal (e.g., attendance at scholarly meetings) training. In particular doctoral programs aim to initiate students progressively into more independent work and autonomous thinking that helps develop professionals who can both master knowledge and produce original work (see Sullivan, 1991). Research on doctoral education makes clear that professionalization depends not just on the quality of the substantive curriculum and research training but also on the quality of advising, mentoring, and peer relationships (see, e.g., Nettles and Millett, 2006).

Variation and Change in Social Science Professionalization

Beyond the shared norms of science that transcend any one discipline, scientific fields differ as to their intellectual tasks, their methods of inquiry, and how their work is done and rewarded (see Austin, 2002). For example, chemistry in comparison to sociology has a longstanding tradition of intensive collaboration on more tightly defined problems. Thus, chemistry students are more closely supervised, work in research teams, and are involved in joint publication. Sociology

students have more variable sets of exposure – from large-scale teams to research environments with intermittent contact with advisors, more independent work, and less engagement in collaboration. Sociology students, however, work and publish more collaboratively than do anthropology students, who are in a field more influenced by single investigator, ethnographic research (Babchuk et al., 1999).

Also, it is important to recognize that professionalization is a dynamic social process. As higher education and social science professions have changed over time, the aims and ambitions of professionalization have also transformed. Graduate programs are still primarily anchored on socializing the next generation of scientists and scholars who can contribute to knowledge production. This longstanding purpose, however, has expanded to include broader aspects of research training (e.g., exposure to peer review, considerations of ethical conduct, oral and written communication). Also, beyond an emphasis on research, there is increasing attention to other aspects of scientists' roles and responsibilities (e.g., teaching, service, human rights) as well as to professional opportunities in settings outside of the academy.

Enrollment and Degrees in the Social Sciences

Bachelor's Degrees

Undergraduate majors in social science fields constitute the potential pipeline of those who might be attracted to and eligible for becoming social scientists. They also are an important 'constituent' group because the number of majors in a discipline shapes the demand for trained faculty members in that area in the academic workplace. Even with only a bachelor's degree, they represent a sector of the future workforce that may ultimately supply jobs classified as social science occupations (ostensibly among those positions that do not require more advanced expertise or skills).

Compared to majors in mathematical, physical, and biological sciences, undergraduates typically declare majors in the social sciences later in their academic careers. This is primarily attributable to the scarce attention given to the social sciences as fields of science in the elementary and secondary school curricula. Therefore, many undergraduates have their first exposure to these fields as a part of fulfilling their general education requirements.

Despite later exposure to these fields, the social sciences confer a substantial number of bachelor's degrees. In 1980, even excluding psychology, bachelor's degree production was higher in the social sciences (93 119) than in the next highest field of science and engineering (63 942 biological and agricultural sciences bachelor's degrees). Thirty years later, in 2010, bachelor's degree production (again excluding psychology) continued to be higher in the social sciences (163 071) than in other science and engineering fields (see S&ED, 2013: Table 5).[3]

Bachelor's degree production varies considerably within the social sciences. As shown in **Table 1**, from 1980 to 2010, bachelor's degree production was substantially larger in psychology than in any other social science field, with political science also sizable. Furthermore, degree production increased over these three decades, but the rate of increase varied by discipline. While bachelor's degree production in economics increased by 47.4%, in psychology it increased by 129.9%.

The varying growth rates of disciplines within the social sciences have resulted in changes over time in the share of social science degrees awarded by individual disciplines. For example, bachelor's degrees in psychology accounted for 31.3% of all bachelor's degrees awarded in the social sciences in

Table 1 Degrees awarded in the social sciences by level, select years, 1980–2010

1980, but, by 2010, this share had increased to 37.4%. In contrast, economics bachelor's degrees decreased from 14.6% of all bachelor's degrees awarded in the social sciences in 1980 to 10.9% in 2010.

Graduate Enrollment

As can be seen in Table 2, graduate enrollment in the social sciences has grown steadily over the past three decades, fueled in part by increases in bachelor's degree production in these fields. At the graduate level, enrollment in the social sciences increased from 121 441 in 1980 to 166 147 in 2011 – up by 36.8%. Graduate enrollment is also larger in the social sciences than in all other science and engineering fields, with enrollees in social science fields accounting for 29.6% of all science and engineering graduate students. While the size of graduate student enrollment in the social sciences is substantial, the growth in enrollment of engineering graduate students over the 1980 to 2011 period approximately doubled, making it a close second.

Master's and Doctoral Degrees

As with bachelor's degree production, across all fields of science master's and doctoral degree production has visibly increased since the 1980s (see S&ED, 2013: Tables 12 and 19). In the social sciences, master's degree production overall increased from 1980 to 2010, largely attributable to substantial growth in political science and psychology (see Table 1). Master's degrees in engineering also grew substantially within this time frame.

At the doctorate level, degree production in the social science disciplines has grown only modestly, largely attributable to an increase in doctorate degrees in political science and in the broad category covering other social science fields. While in 1980 doctoral degree production in social sciences fields (6470) was larger than in other science and engineering fields, by 2010, degree production in social sciences (8234) was outpaced by production in biological and agricultural sciences (9036).

Within the social sciences, there were variations in doctoral degree production by discipline (see Table 1). Over the period from 1980 to 2010, the number of doctoral degrees awarded in psychology was substantially higher than in other social science disciplines. In 2010, psychology conferred 3421 doctoral degrees, five times more than sociology and nearly three times more than economics (although about 40% of the psychology doctorates awarded in 2010 were clinical doctorates). While doctoral degree production in psychology continues to outpace degree production in other social sciences fields, the rate of increase in psychology over the 30-year period (10.4%) is lower than in political science (64.8%), other social sciences (59.8%), and economics (28.4%).

Doctoral Degree Completion and Time-to-Degree

The duration of doctoral education remains a concern in higher education despite a decrease in time-to-degree over the last two decades. Based on the most recent data available from the National Science Foundation (see S&ED, 2010: Table 31), doctoral students in the social sciences tend to take longer to complete their degrees than students in other fields of science and engineering. In the social sciences, the median time-to-degree in 2010 was 7.7 years; this figure trailed the physical sciences (6.7 years), life sciences (6.8 years), and engineering (6.9 years). Doctoral students in the social sciences, however, typically complete their doctorates more rapidly than those in humanities, where the median time-to-degree in 2010 was 9.3 years.

Moreover, completion rates are a significant consideration (see Table 3). According to the Council of Graduate Schools (2008), approximately 56% of social science doctoral students and 55% of doctoral students in mathematics and the physical sciences complete their degrees within 10 years. These rates are visibly lower than the ones of doctoral students in engineering (64%) and the life sciences (63%). All fields of science and engineering, however, have a higher 10-year completion rate than in the humanities (approximately 49%).

Financial support for doctoral students is a relevant factor in considering time-to-degree and lower completion rates. On average, doctoral students in social sciences receive less non-loan financial support than students in other fields of science and engineering. According to 2010 data from the National Science Foundation (S&ED, 2010: Table 35), doctoral students

Table 3 Cumulative 10-year completion and attrition rates for students entering doctoral programs between 1992–93 and 1994–95, by broad field

	Rates by years since entering program

in the social sciences are more likely to primarily finance their doctoral education through their own resources (27.1%) compared to students in physical sciences (4.4%), engineering (4.5%), and life sciences (8.9%). As a result, 60.8% of social sciences doctorate recipients in 2010 graduated with debt, compared with fewer than half of the doctorate recipients in other fields of science and engineering (S&ED, 2010: Table 38).

Diversity and the Doctoral Degree

Gender

Since the 1980s, there has been a dramatic increase in women receiving doctoral degrees across all fields of science and engineering (see S&ED, 2013: Tables 19, 23, 25, 35, 40, 41, and 46). In 2010, 13 548 women received science and engineering doctoral degrees, a number which is more than three times higher than the 3961 women who earned such degrees in 1980. These numbers also represent a substantial difference in the shares of all science and engineering doctoral degrees awarded to women (40.9% of all science and engineering degrees in 2010 compared to 22.3% in 1980). Furthermore, fields vary considerably in the proportion of doctorates awarded to women, with the social sciences and the biological sciences conferring a much higher proportion of doctorates to women than the physical sciences and engineering.

There are notable differences within the social sciences as well (see S&ED, 2013: Tables 40, 42–45). In 1980, men earned the majority of the doctorates awarded in all social science fields, with psychology having the highest percentage of degrees earned by women (42.3%) and economics the lowest (12.5%). By 2010, women earned the majority of the doctorates awarded in psychology (69.8%), sociology (60.8%), and other social sciences (54.8%), but earned well under half of the degrees in political science (42.9%) and economics (34.5%).

Race/Ethnicity

The data on earned doctorates for racial and ethnic minorities who were US citizens or permanent residents were first reported in the 1970s. In 1980, across all fields of science and engineering, the number of persons of color receiving doctorates was quite small (814, or 6% of all doctoral degrees awarded to US citizens in science and engineering fields; see Hoffer et al., 2001: Table 8). The numbers of minorities earning doctorates in science and engineering and the proportion of science and engineering doctorates earned by minorities increased noticeably over the next three decades (S&ED, 2010: Table 23). By 1990, minorities earned 1963 science and engineering doctorates (or 12.3% of all science and engineering doctorates awarded to US citizens and permanent residents). By 2010, this number more than doubled to 4584 science and engineering doctorates (21.5%).

There are important differences across fields of science in the proportion of doctorates awarded to racial/ethnic minority groups (see S&ED, 2010: Table 23). Of the doctorates earned in engineering in 2010, 16.9% were Asians and 4.2% were black[4]; similarly, Asians received 10.5 and 11.1% of the doctorates, respectively, in the physical and life sciences, with blacks receiving only 3.0 and 5.1% of the doctorates in these fields. In contrast, greater balance across racial/ethnic minority groups is evident in social science fields. The percentage earning doctorates is more than 6%, respectively, for Asians, blacks, and Hispanics. The proportion of American Indians/Alaska Natives earning doctorate remains low (well under 1%) across all broad fields (see S&ED, 2010: Table 24).

Across the social sciences, racial/ethnic minorities differ in the percent of doctorates being earned (see S&ED, 2010: Table 24). For example, in 2010, economics and sociology awarded 22.7 and 22.3% of their doctorates, respectively, to racial/ethnic minorities, with psychology and political science somewhat lower at 19.2 and 18.3%, respectively. In contrast, anthropology was considerably lower – awarding only 14.7% of its doctorates to racial/ethic minorities. Asians earned higher proportions of doctorates in economics (11.8%) than in other social science fields, while blacks earned their highest share of doctoral degrees in sociology (8.9%).

Non-US Recipients

The numbers of non-US citizens on temporary visas earning doctorates in science and engineering almost doubled over the past three decades (see **Table 4**). In 2010, non-US citizens earned 33.4% of all science and engineering doctorates awarded in the US, up from 15.6% in 1980 (see S&ED, 2010: Tables 18 and 22). Across broad fields of science and engineering, there is considerable variability in the proportion of non-US recipients of doctorates – ranging from approximately 26% in the life sciences to 51% in engineering. In the social sciences, the shares of doctorates earned by non-US citizens are overall lower than in other fields of science. International students earned 8.9% of all social science doctorates in 1980 and 19.9% in 2010. Within the social sciences, however, there is also variability. Non-US citizens earned the highest share of doctoral degrees awarded in 2010 in economics/econometrics (51.8%) and the lowest shares in psychology (7.9%).

Table 4 Science and engineering doctorates earned by non-US citizens on temporary visas, 1980 and 2010

	1980			2010		
Broad field	*Total doctorates*	*Non-US citizen doctorates*	*Percent non-US citizen*	*Total doctorates*	*Non-US citizen doctorates*	*Percent non-US citizen*

International Comparisons in Doctoral Degree Production

As is the case with doctoral degree production generally, doctoral production in the social sciences is higher in the US than in all other countries (see Table 5). In 2008, the latest year for which comparable data are available, over 8900 doctorates were awarded in social sciences in the US (National Science Board, 2012). Russia awarded the second largest number of social science doctorates (over 6800), followed by China (2270), South Korea (2240), and the United Kingdom (2230). In 2008, the US ranked second in terms of the share of all science and engineering doctorates that are in social science fields with 26.7%. First ranked was Russia, with 46.0% of science and engineering doctorates in the social sciences in 2008 (noticeably up from 27.8% in 2000). Also of note is that, while China has a sizable doctorate degree production in science and engineering (in 2008, 28 439 compared to 33 359 in the US), only 8% of the doctorates were in social science.

Source: National Science Board, Science and Engineering Indicators 2012, Appendix Tables 2.37 and 2.38.

Current Patterns for New Doctorate Recipients

Across all fields, about 57% of new doctorate recipients in 2010 with postgraduation plans had plans for employment; the remaining 43% had plans for postdoctoral study (S&ED, 2010: Table 44). In the social sciences, a slightly smaller share (35%) had plans for postdoctoral study. In the social sciences, as in other fields, increasingly larger shares of newly minted doctorates are pursuing postdoctoral study over time. The shift has been substantial. For example, the share of new doctorate recipients in social sciences pursuing postdoctoral study grew from 15.7% in 1990 to 23.9% in 2000 and to the 35% noted for 2010.

Social science doctorate recipients are also more likely to enter the academy than doctorate recipients in other fields of science and engineering (S&ED, 2010: Table 46). Among new social science doctorate recipients in 2010, 59.9% took positions in the academy immediately after the receipt of the doctorate, compared with 52.6% of all new doctorate recipients. Also, while the share of all new doctorates entering the academy has been relatively stable over the past two decades, in the social sciences, the share of new doctorate recipients entering academic employment has increased, rising from 50.3% in 1990 to 59.9% in 2010.

The Social Science Labor Force

As noted in the introduction, the labor force includes those persons who are economically active – either employed, or, if unemployed, available for work. In 2010, according to the Current Population Survey conducted by the US Census Bureau, approximately 154 million persons were active in the civilian workforce of the US, including 15 million unemployed persons (Bureau of Labor Statistics, 2011). Social science professionals constitute only a miniscule segment of this overall labor force (less than one-half of 1%) if such professionals are defined as persons having an advanced degrees (a master's or doctoral degree) in a social science.

Employment Status of Social Scientists

The overall employment status of those with advanced degree training in the social sciences is quite favorable. According to the National Science Foundation's Scientists and Engineers Statistical Data System (SESTAT), there are about 1 050 000 social science professionals in the labor force (835 000 at the master's level and 218 100 at the doctoral level). Employment rates for these individuals are strong. In 2010, only 2.0% of doctorate-level social scientists and 5.5% of those with a master's degree were unemployed (see SESTAT, 2010[5]) – considerably below the overall 9.6% unemployment rate in the US in 2010 (Bureau of Labor Statistics, 2011). Among doctorate-trained social scientists, the vast majority (about 83%) was employed full-time (see SESTAT, 2003), and about 75% are employed in science and engineering occupations, primarily in social science occupations (see SESTAT, 2010).

Social Science Occupations and Professional Training

The labor force in the social sciences can be conceptualized as (1) those persons *trained* in the social sciences or (2) those persons *working* in social sciences *occupations*. In contrast to a focus on degree training per se, classification into occupational categories includes persons trained in other fields who are working in these areas but excludes persons with relevant training who are working in other occupational areas (see National Science Foundation, 1999). For example, social science occupations would include persons with doctorates in business who are teaching sociology in a university but would exclude persons with doctorates in sociology managing a business.

SESTAT classifies persons into occupations in terms of both work and education. Based on the SESTAT surveys, in 2010, approximately 518 100 persons with a bachelor's degree or higher were classified as being in a social science occupation. This occupational category includes jobs that vary widely as to the nature of the work and required expertise. Two-thirds (67.3%) of the individuals in social science occupations received their highest degree in a social science field. Furthermore, having an advanced degree beyond the bachelor's level also matters: the majority of persons working in social science occupations have an advanced degree (see SESTAT, 2010).

The value of an advanced degree can further be seen by examining the relationship between bachelor's, master's, or doctoral training in a field and working in an occupation classified as being in that same field (i.e., 'in-field' occupation). As shown in **Table 6**, for all fields of science, persons at successively higher degree levels are more likely to be working in occupations classified as 'in-field.' In the social sciences, 1.8% of those persons with bachelor's degrees were working in a social science occupation, compared to 17.2 and 64.5%, respectively, of individuals with master's and doctoral degrees. Moreover, doctoral degree training really matters in social science fields. In comparison to other fields of science and engineering, individuals with bachelor's and master's training have a very low presence in an in-field occupation. At the doctoral level, there is far less variability across fields of science and engineering in the proportion of persons working in 'in-field' occupations.

Sectors of Employment

Examination of doctorate-level professionals in the social sciences shows the centrality of the academic workplace in relation to other work sectors. Four-year colleges and universities are the dominant employer of doctorate-level scientists and engineers. Across all science and engineering fields in 2010, 45.0% of doctorate-level scientists and engineers worked at 4-year colleges and universities; in the social sciences, 46.9% did so. Business/industry also employed large numbers of doctorate-level scientists and engineers, but far less so in social science fields. Across all science and engineering fields, 41.9% were employed in business/industry, with only 38.1% of the social scientists employed in this work sector (see SESTAT, 2010).

Although specific disciplines within the social sciences followed this overall pattern, there are important differences. As shown in **Table 7**, in 2010, more doctorate-level sociologists and anthropologists (70.7%) were employed in 4-year colleges and universities than were social scientists in other fields. In contrast, greater proportions of psychologists (48.4%) and economists (39.9%) were employed in business/industry. For psychologists, this is ostensibly due to the sizable number of psychologists who are in clinical practice.

Wages in Social Science Professions

Overall, annual median wages for social scientists are in the same range as other science and engineering fields. In 2012, in US dollars, the median wages for social science professionals were $69 280 for psychologists, $74 960 for sociologists, $91 860 for economists, and $107 420 for political scientists. Other fields of science and engineering report such median 2012 wages as $66 260 for microbiologists, $80 580 for mechanical engineers, $101 360 for mathematicians, and $106 840 for physicists (see Bureau of Labor Statistics, 2014).

Table derived from analyses of data in SESTAT, an online database. For information on the specific SESTAT variables used, please contact the principal author.
Source: National Science Foundation, Scientists and Engineers Statistical Data System (SESTAT).

These occupations include scientists at all education degree levels, as set forth in the 2014 Bureau of Labor Statistics (BLS) *Occupational Outlook Handbook*. For scientific and engineering fields, the entry-level education is typically at least a master's degree. These salaries are in line with salaries of other occupations with typical education requirements of a master's degree or a doctoral or professional degree (Lockard and Wolf, 2012: Table 6).[6]

Women and Minorities in the Social Science Labor Force

Gender

Of the 213 800 employed doctorate-level social scientists in 2010, 52.8% were male and 47.2% were female (see SESTAT, 2010). Employed female social scientists, however, are more likely than employed male social scientists to have received their doctoral degrees in recent years. For example, among social scientists who received their degrees between 1976 and 1980, approximately 70.7% were male. In contrast, of those who received degrees in 2006 or later, only 38.4% were male (see SESTAT, 2010). This pattern holds true in all social science disciplines, with women accounting for larger shares of more recent cohorts than earlier cohorts of employed doctorate-level professionals (see SESTAT, 2010).

Males and females with doctorates in the social sciences vary only modestly in terms of sectors of employment. Gender differences within disciplines are more striking than the overall trends. For example, a higher proportion of male than female economists was employed by 4-year colleges and universities (49.6 vs 42.1%), while a higher proportion of female than male sociologists and anthropologists were in business/industry (21.7 vs 15.0%) (see SESTAT, 2010).

Race/Ethnicity

Of the 213 800 employed doctorate-level social scientists in 2010, 81.2% were white, non-Hispanic; 11.8% were underrepresented minorities (African-American, Hispanic, or Native American), and 7.0% were Asian.[7] The data on doctorate-level social scientists of color in the workforce are consistent with the increase in the production of minority doctorates since the mid-1970s (see SESTAT, 2010). Of those in the workforce in 2010 who received their doctoral degrees between 1976 and 1980, 90.2% were white, non-Hispanic, 6.6% were underrepresented minorities, and 3.1% were Asian. In comparison, of those in the workforce receiving degrees since 2006, 72.6% were white, non-Hispanic, 17.5% were underrepresented minorities, and 9.96% were Asian (see SESTAT, 2010).

Employment sector data also point to important differences between minority and white doctorate-level social scientists (see SESTAT, 2010). In 2010, higher proportions of Asians (53.7%) and underrepresented minorities (51.4%) were employed at 4-year colleges and universities than white, non-Hispanics (45.7%). In contrast, a higher proportion of white, non-Hispanics were employed in business/industry (39.5%) than Asians (33.2%) and underrepresented minorities (31.6%). The higher proportions of minority doctorates employed in higher education compared to white doctorates may reflect efforts by the academic sector to diversify its workforce in the context of a low number of doctorates of color being trained.

Looking Ahead for the Social Science Professions

This article has provided an overview of basic patterns and trends in the preparation and employment of social science professionals. Enrollment and degree patterns suggest that the supply of new social scientists will remain strong at least for the foreseeable future. The current picture and projections also suggest that overall degree production will be met by employment opportunities in academic and nonacademic work sectors. Furthermore, among social science professionals at the doctorate level, higher education will continue to be the dominant employer for social scientists.

Psychology is the one exception. As has been the case for more than a decade, psychology (by far the largest of the social science professions) has a larger footprint in business/industry than in the academy, consonant with doctorate training in clinical, practice, and organizational specializations. The proportion has remained relatively stable for quite some time. In both 1997 and 2010, approximately 48% of psychologists were employed in business/industry and 34% were in 4-year colleges or universities. While for economists the academy still remains the primary employer at 47.8%, that number is down approximately 10% and business/industry is up approximately 10% since 1997 (see Survey of Doctorate Recipients, 1999: Table 17; compared to **Table 7** above).

Looking ahead, the BLS anticipates a relatively strong labor market for social scientists (Bureau of Labor Statistics, 2012). Between 2010 and 2020, BLS projects a 22% increase in new jobs for psychologists, an 18% increase for sociologists, an 8% increase for political scientists, and a 6% increase for economists. In addition, demand for postsecondary teachers, a major occupation for social scientists, is expected to increase by 17% between 2010 and 2020.

Employment opportunities and the salary picture also suggest that social science professions are among the occupational groups that will expand somewhat over the years ahead. The data indicate that the growth observed in the 2010–12 period is not merely growth in new jobs to recover jobs lost during the recession that hit especially hard in 2009. There was indeed overall growth in employment of 4.8% across all fields of life, physical, and social science occupations between 2006 and 2010 (see Lockard and Wolf: Table 1). This growth placed it in the top 3 of 22 major occupational groups – at a time when 12 of these groups experienced declines.

Because social science professionals at the doctorate level are primarily engaged in scientific research, their capacity to pursue the work that motivated entry into their professions is inextricably tied to the conditions of higher education and the availability of research funds. The current period is a time of uncertainty. Higher education institutions are seeking to provide accessible, affordable, and excellent education. Moreover, they are focused on modernizing their infrastructure and technology, and, at least for research-intensive institutions, serving as environments that can support scientific and scholarly productivity, creativity, and innovation under rapidly changing conditions of accountability, financing, and governance in the US and worldwide (see, e.g., Altbach, 2013; Arum and Roksa, 2011; Bok, 2013; Zumeta et al., 2012).

While higher education is undergoing a restructuring, it is also important to keep in mind that the academy is segmented into different types of institutions that employ social science professionals for missions that vary in function and purpose. The forms of work for social science professionals in diverse academic markets (e.g., research universities, liberal arts colleges, 2-year colleges) may change as higher education overall transforms and as sectors of the academy undergo specific changes. Increases in student–faculty ratios, more use of part-time or contractual appointments, or the increased inclusion of massive open online courses are just some of the contingencies that could shape the lives of social science professionals in the academy in the next decade.

Research funding also continues to be a salient consideration to the work of social science professionals. The US federal government provides substantial funding each year for basic and applied research (see National Science Board, 2012: Tables 4–35).[8] Over a 20-year period, however, funding obligated for social science research has been a small proportion of the total. In 1989, $20.77 billion was invested in research in science and engineering fields – with 4.68% allocated to psychology and the other social sciences. In 2009, the overall federal obligations grew to $63.7 billion, with the share to psychology/social science dropping slightly to 4.09%.

Within psychology/social sciences, psychology has over time received more federal funding than the other social science fields (accounting for 3.27% of the 4.09% in 2009). In comparison to the life sciences that receive over half of federal funds for basic and applied research or to the medical sciences or engineering that each receive better than 15%, the psychology investment is quite limited. Psychology, however, along with mathematics and computer sciences, has had one of the larger growth rates across scientific fields (8.3%) over the same 20-year period.

Despite areas of uncertainty, the overall picture for social science professions is favorable. The issues these fields examine and the theories and methods they bring to the study of human, social, and institutional processes hold promise of advancing knowledge that is valuable worldwide. Attention earlier in children's education to developing an appreciation for and savvy in these sciences would further attract talented undergraduates and also expand policy maker and public understanding of the contributions and significance of these fields.

End Notes

1. The term 'social science' as used in this article is intended to mean the social and behavioral sciences. These sciences include a range of disciplines and fields addressed to human and social processes. This article focuses primarily on four professional social science fields (economics, political science, psychology, and sociology) where sufficient national data are available in the United States to examine general trends and contrast these fields to other scientific professions.
2. Although, as noted earlier, scientific and academic professions are distinct, socialization for both are an integral part of the graduate education process. Students are exposed to the features, opportunities, and requirements of academic professions, even if their aspirations as social science professionals lie outside of the academy.
3. Psychology attracts substantial interest among undergraduates – many of whom are drawn to the possibility of clinical or counseling occupations. In 1980, there were 42 513 bachelor's degrees awarded in psychology; in 2010, there were 97 746 psychology bachelor's degrees.
4. The term 'black' as presented in the data table in S&ED (2010) refers to US citizens and permanent residents who are black/African American.
5. In prior releases of SESTAT, data were available in published tables. The 2010 data, however, are only available in a database where analyses need to be performed. For further information on the specific variables used in any calculations from SESTAT, please contact the principal author.
6. At the time of this writing only 2010 wage data are available for occupations by level of education. The median annual wage for a master's degree is $60 240 and for a doctoral or professional degree is $87 500.
7. These figures drawn from SESTAT (2010) include US citizens and permanent residents, as well as non-US citizens on temporary visas.
8. In 2009, the federal investment for basic and applied research was $63.7 billion – about 48% of the total federal investment in research and development (National Science Board, 2012: pp. 4–33).

Abstract

Can human studies be scientific? The question is addressed by considering four others. What does it take for a subject to be scientific? Why does the issue matter? What are the impediments to human studies achieving standing as sciences? How are human studies to be classified if not as sciences? The potential impediments are the complexity of human phenomena, their instability over time, and the fact that they are always already 'pre-interpreted' by ordinary social agents. Alternative understandings of human studies are: literature, critique, and ideology. Crucially, the issue matters because of the institutional status which being a science confers.

Introduction

Can human studies, such as sociology and psychology, be properly scientific? This question is considered in four stages: (1) What does it take for a subject to be considered scientific? (2) Why does the issue matter? (3) What are the impediments to human studies achieving standing as sciences? (4) How are human studies to be classified if not as sciences? In relation to question (1), the importance of objectivity is stressed. In relation to question (3), three factors are identified: the complexity of human phenomena, their instability over time, and the fact that they are always already 'pre-interpreted' by ordinary social agents. In relation to question (4), human studies are compared to literature, to critique, and to ideology. And why does the issue matter? Because of the institutional status which being a science confers; because how human studies are classified influences where they look for models of their own activities; and because granting human studies the same cognitive authority as are enjoyed by some of the paradigm sciences may have morally repugnant implications.

Can human studies, e.g., sociology and psychology, be properly scientific? Since the mid-nineteenth century, philosophers and social scientists have debated this question more or less continuously. It has periodically assumed considerable urgency, indeed become a focus of attention within the disciplines, as new influences on these subjects were felt or as new models of science itself were developed. Indeed, the complexity and potential obscurity of the issue is already evident. There is an implied equation, "*human studies* are/are not *science*," in at least two variables. There has been considerable debate, at least since the 1850s, about what kinds of roles human studies might play. Likewise, what is required for a discipline to be scientific has also been a matter of continuing controversy. As Peter Manicas put it (1987: p. 168), "neither 'science' nor, a fortiori, the branches of the social sciences are 'natural kinds.'" Notice, furthermore, that the variables are not entirely independent of one another. What human studies practitioners have aspired to has itself been influenced by what they think about the desirability and the possibility of making their enterprises genuinely scientific. Similarly, though perhaps to a lesser extent, what has counted as scientific has reflected the actual practices of, inter alia, students of sociology and psychology. To approach this question, a suitably sophisticated taxonomy of possibilities is therefore required.

Some Taxonomic Distinctions and a Definition

If human studies are to count as scientific, then what it takes to make a science must first be considered.

Modality

First, *empirical* and *normative* approaches to this question need to be distinguished – roughly, "What are the sciences like?" and "What should the sciences be like?" Of course, these two questions cannot be treated in isolation, especially in view of the widely accepted maxim that "*Ought* implies *can*." This maxim means, in this instance, that those subjects whose scientific status is being assessed cannot sensibly be required to attain some excellence unless, of course, *paradigms* of scientific achievement have themselves attained this excellence.

There are, in fact, some further difficulties as the 'paradigm' sciences are not only not 'natural kinds,' they in fact exhibit some diversity among themselves (Whitley, 2000: pp. 121, 123) in relation to "the stability of problem formulations," "the extent to which work techniques are well understood and produce reliable results," and (Becher, 1989: pp. 87–88) the degree to which there is a diversity of niches into which individual enquirers separate themselves.

With these points in mind, the question about human studies can be understood in this way: Given what human studies *are* like, do they or can they conceivably measure up to whatever normative standards of excellence the best scientific disciplines *do* measure up to?

Focus

Of course, there are other issues about what it takes to make a science. The question of focus is perhaps the most important. Science and nonscience can be distinguished either in terms of their *products* or in terms of their *processes*. This fundamental distinction divides pre- and post-Kuhnian conceptions of science. Whereas *before* Thomas Kuhn's epochal work *The Structure of Scientific Revolutions* (1970),

science was distinguished from nonscience by the kinds of *statements* the two discourses produced, or, more importantly, by the status of these statements relative to epistemic standards of confirmation, generality, or objectivity, *after* this work, science was increasingly distinguished from nonscience in terms of the activities of its practitioners. Obviously, it will make a difference which of these criteria is deemed more appropriate. On the product conception, it might count against the scientific pretensions of sociology and psychology, for instance, that the more robust results in these subjects lack the kind of generality that robust results typically display in paradigm, 'hard' sciences such as physics and chemistry. But perhaps this lack of generality is irrelevant if a process criterion is adopted. Perhaps sociologists and psychologists obtain their less general findings by the same technical means and methods that natural scientists use in producing more general or more stable results.

Scope

Finally, there is the issue of scope. Roughly speaking, *wide* and *narrow* understandings of the sciences can be distinguished. On the narrow reading, it is the concrete and specific particularities of the paradigm sciences that provide criteria for judging other candidate sciences. Typically, the paradigm sciences are laboratory based, involve heavy reliance on statistical techniques of data analysis, and produce results in the form of highly confirmed differential equations relating measurable variables. On the narrow criterion, then, to count as a science, any other discipline must also exhibit these specific features. On the other hand, a wide approach to the issue requires of candidate sciences merely that they exhibit some abstract and high-level virtue which is shared by paradigm scientific achievements – that they permit the attainment of objectivity, for instance. A wide approach to the issue is probably indicated; at the concrete and specific level of technique and theory, there is enough variation *within* the paradigm sciences to rule out any narrow approach.

In considering whether human studies are scientific, an approach which is normative, process oriented, and wide in its scope should therefore be adopted. The question will be, in other words, whether it is possible that human studies be conducted in such a way that they might achieve whatever levels of objectivity in their procedures as are attainable in the paradigm sciences. (The issue is phrased in this way to permit the rather complicated judgment (likely to be favored by 'postmodernists') that human studies can achieve the same *degree* of objectivity as paradigm sciences, but that neither can achieve the *kind* of 'objectivity' that was previously thought to be characteristic of paradigm, natural sciences such as physics.)

Objectivity

To assess the scientific status of disciplines such as sociology and psychology, the objectivity of their procedures must, on this account, be assessed. But what is objectivity? Of course, there may be no more determinacy on this matter than on some others which have already been alluded to. Just as 'science' does not designate any natural kind, neither does 'objectivity'; it will be a matter of persistent debate what counts as objective. Some preliminary observations can nevertheless be offered.

First of all, transcendental and nontranscendental accounts of objectivity can be distinguished. In the transcendental account, objectivity in investigative activities has been attained when and only when all that is specific to the situation in which they are undertaken, including the personalities of the investigators, has been eliminated from them. Individuals who are otherwise dissimilar must, on this account, conduct themselves in some common way when they examine the objects of their investigations. (When scientists have managed to specify methods for the replication of results, some approximation to this ideal may have been achieved.) They know how to tell others who differ from them, how to negate the effects of these differences, and thus achieve the same results as they have. Objectivity, on this account, consists of transcending local circumstances by eliminating all factors that vary from one situation to another.

Of course, philosophers and others working under the rubric of 'postmodernism' have widely repudiated this ideal. True transcendence of local circumstances is not possible, it is not desirable, and, indeed, it is not even necessary for a form of objectivity (that is worthy of being pursued) to be attained. Objectivity requires not that local differences be eliminated, but, rather, that they be exploited in order to discover, where this is possible, a point of convergence of otherwise very different perspectives. According to this account, objectivity is attained when an individual is able to affirm from his or her own perspective a system of propositions that can likewise be affirmed from the otherwise different perspectives of such other individuals whose agreement matters (see Rorty, 1989).

Why the Issue Matters

Why should it matter whether human studies are or are not scientific, especially if there is little agreement about the concepts in terms of which the issue is defined. Discussing the so-called 'interpretive turn' in human studies, Geertz (1993: p. 8) put the point this way: "Whether this [development] is making the social sciences less scientific or humanistic study more so (or, as I believe, altering our view, never very stable anyway, of what counts as science) is not altogether clear and perhaps not altogether important." There are, in fact, at least three reasons why it matters whether human studies are considered scientific.

Institutionally

The scient*ism* of its public culture, i.e., the privilege that is granted to scientific disciplines and their methods and results, is one prominent characteristic of modernity. Science has immense, though perhaps no longer undisputed, cognitive authority, and plays an influential role in defining as well as creating the world that human beings inhabit. If human studies succeed in gaining recognition as scientific subjects, then they too could hope to exercise this kind of authority. Foucault, typically, puts the matter the other way around (1980: p. 85): "What types of knowledge do you want to disqualify in the very instant of your demand: 'Is it a science?' Which speaking,

discoursing subjects of experience and knowledge do you want to 'diminish' when you say: 'I who conduct this discourse am conducting a scientific discourse, and I am a scientist?' Which theoretical-political *avant garde* do you want to enthrone in order to isolate it from all the discontinuous forms of knowledge that circulate about it?"

Heuristically

Whether sociologists and psychologists see themselves and are seen by others as scientists will, of course, influence the conduct of their enquiries and the kinds of products they aspire to deliver. As Geertz (1993: p. 8) put it, the issue is "who borrows what from whom." Do human studies borrow techniques of observation, experimentation, and data manipulation from 'hard' sciences such as chemistry and biology, or do they, instead, look to other disciplines for their techniques or their standards of objectivity?

Indeed, this issue is part of a long-standing debate. In the late nineteenth century, the crucial questions were about the *Geisteswissenschaften* – are they concerned with understanding or with explanation? Can they articulate general psychic and/or social laws or must they, instead, confine themselves to the accurate description and contextualization of concrete and specific incidents (Windelband's *nomothetic* vs *idiographic* conceptions)? In the middle of the twentieth century, the key issue was the cognitive status of social scientific generalizations and, indeed, their very possibility in the face of innumerable obstacles and points of difference from paradigm 'hard' sciences. At the end of the twentieth century, the question is whether interpretation, with all its vicissitudes, constitutes a more central method for human studies than law-based explanation, and, indeed, whether interpretation itself is possible in a sufficiently 'objective' manner to permit the judgment that human studies are, perhaps in some extended sense, scientific. Another possibility, of course, is to acknowledge what is anyway already present in the hard sciences, namely, a kind of explanatory project that aims, not at the explanation of events, but, rather, at the explanation of patterns or regularities. So, for instance, statistical mechanics does not aim at the explanation of the trajectories of individual particles, but, rather, at the explanation, in terms of a small number of measureable variables of the patterns found in ensembles of these particles. Similarly, a scientific approach to social studies might aim at this kind of explanation, as, indeed, Hayek (1967) has advocated and as has been common, in the social sciences, *both* in the form of the explanation, via regression analysis, of trends in large corpora of data about individuals or prices or indeed any of the explananda of the social science *and*, more recently, in the form of agent-based modeling and, hence, the *generative* explanation of patterns and trends in multi-agent phenomena. (See for example Epstein, 2006.)

Morally

How human studies are conceptualized may have profound moral significance. This point is dependent on the previous two. Suppose human studies are modeled on the 'hard' sciences and that success in doing so is conspicuous enough so that these subjects gain the kind of cognitive authority that some of their practitioners have long aspired to. In this case, ideas about the human situation that are moral and cultural foundations of our longest-standing and most deeply embedded traditions are at risk of being undermined. Putnam (1978: p. 63) put it this way: "[S]uppose our functional organization became transparent to us. Suppose we had a theory of it, and we could actually *use* this theory in a significant class of cases. What would happen to us? … Would it be possible even to think of *oneself* as a *person*? … [T]he development of *that* sort of knowledge of ourselves and each other would modify our natures in ways that we cannot predict at all. Every institution we now have: arts, politics, religion – even science – would be changed beyond all recognition."

Some Positions

Whether human studies can be scientific is therefore too important a question simply to ignore. And, of course, it has not been ignored. Philosophers, social scientists, and others have, in fact, taken a number of positions on this question. Before proceeding with more substantive matters, a threefold primary distinction among these positions should be considered.

In the middle of the twentieth century, the most common position, though not so designated until later, was *naturalism*. According to this doctrine, there is nothing methodologically or theoretically distinctive about human studies in relation to paradigm, natural sciences. In particular, social and natural scientists legitimately share both aspirations (to discover and confirm general laws covering specific phenomena) and techniques (operationalization of variables, controlled experimentation, and statistical analysis of its results).

Both earlier and later than this period, however, a very common, perhaps even the most common position was *interpretivism*. According to this doctrine, human studies are distinguished from paradigm, 'hard' sciences both in their aspirations and in their techniques. Social scientists should not try to emulate the paradigm sciences narrowly construed (see Section Scope); they should strive, instead, to interpret human social and psychic phenomena, and should employ the techniques of hermeneutics, broadly construed, to achieve this.

Finally, toward the end of the twentieth century, though also but to lesser degrees at earlier periods, 'skepticism' about the social sciences has been an increasingly influential position. On this account, the laws of human being cannot be discovered, nor can properly objective interpretations of what human beings do be provided. Although the results of sociological or psychological research are often presented in the form of statements of knowledge, they are not entitled to this status, and must be understood in some other, less exhaulted way.

Skeptical positions may be either local or global. Global skepticism, often associated with the work of Jacques Derrida, repudiates all claims to determinate and methodologically adequate knowledge of human phenomena. Local skepticism adopts such a dismissive attitude only to certain claims, e.g., those that have been derived in some specific way or from some specific social position. (For instance, Marxists might be skeptical in this local sense about the claims produced by mainstream, and hence in their view 'bourgeois' sociology or psychology. Similarly, feminists are often skeptical about the

claims of mainstream and hence in their view 'patriarchal' social science.)

Impediments to Human Studies Being Scientific

That the legitimacy of human studies has so long been a matter of discussion is prima facie evidence that the investigation of human phenomena is not straightforward. What, then, are some of the reasons why it might not be possible to have a genuinely scientific approach to human social and psychic phenomena?

Pre-interpretation

Theorists otherwise as diverse as Peter Winch, R.G. Collingwood, and Alfred Schütz have pointed, in distinguishing human studies from science per se, to the fact that students of human phenomena work, whereas paradigm scientists do not work, with materials that already have meaning and significance (see, e.g., Winch, 1958: p. 87). There are strong and weak versions of this point. On the weak version, students of human phenomena must always rely, methodologically, on the objects of their research in ways in which paradigm scientists need not. Saying *what* is going on is preliminary to saying *why* it is happening, and hence to any scientific explanation. But what is going on, socially or psychically, must be understood, in Geertz's phrase, "from the native's point of view." How the subject understands what is going on determines the description of what is going on. On the strong version, once scientists have characterized "the native's point of view," they have discovered all that they need to or can know about the objects of their investigation. In either case, what paradigm scientists do and what human studies practitioners do is very different. The latter seem forced to rely on the subjective perspectives of the objects of their research. On the other hand, some sorts of scientific approaches to social phenomena are by no means ruled out even if we accept the reliance of social scientists on the conceptual apparatus of the objects of their enquiries. Again, there may be, within the particular conceptual world of the 'native,' discoverable regularities of behavior, whether at the individual or the statistically aggregated level. The scientificity of social enquiry is really only put under pressure by the strong thesis and this thesis is, in fact, itself put under pressure by, for example, the "hermeneutics of suspicion" (Ricoeur, 1970), which posits the unreliability of "the native's point of view" when it comes to understanding the forces and processes of social life.

Instability

There are three interrelated factors which make it unlikely that sociologists and psychologists will be able to develop stable, objective accounts of the phenomena they take an interest in.

First, there is the *historicity* of both the subjects and the objects of human studies research. When Gadamer (1975: p. 204) asks "Is not the fact that consciousness is historically conditioned inevitably an insuperable barrier to reaching perfect fulfilment in historical knowledge?" he articulates this fundamental difficulty: neither scientist nor subject 'stands still,' and hence what the one should say about the other changes as they themselves change. Paradigm, natural sciences, on the other hand, typically deal with statements of 'timeless' generality.

Of course, historicity and scientificity are not incompatible per se, and there is no reason, especially if the focus (see Section Scope) is on process rather than the product, to require the social studies to produce timeless generalizations.

Second, in human studies relations of representation are subject to *reflexivity* in a way that is not common in the sciences per se. What practitioners say about human phenomena influences how their subjects enact or react to these phenomena, and hence often undermines the claim, necessary if objectivity is sought, that scientists have accurately *represented* the behavior of their subjects. (Practitioners have, instead, caused or persuaded subjects to act so that their behavior conforms to the practitioners' descriptions of it.) To mid-twentieth century philosophers, this possibility was best known under the heading 'reflexive predictions' (self-defeating and self-confirming 'prophecies'), but the crucial points have since been generalized extensively. Of course, as Lyotard (1984: p. 57) rightly points out, reflexivity must not be understood in too one-sided a way. It is not just that sociologists and psychologists can create the objects of their investigations; it is, as well, that these objects can, *strategically*, resist the characterizations which practitioners attempt to fit them with. This too is an impediment to the achievement of objectivity as it is usually conceived.

Again, this point is hardly conclusive. Although not uncontroversial, ethically, the use of deception protocols in individual or small-group enquiries and the general invisibility to the population studies of many 'stand-off' observational techniques (e.g., the analysis of large corpora of data) mitigate the effects of reflexivity.

Finally, there is radical *indeterminacy* about the objects of investigation. This point is an ontological not an epistemological one. It is not that, in some or perhaps many cases, scientists cannot tell when they have characterized some phenomenon accurately. It is, rather, that there may be no sense, in these cases, to the very idea of accurate characterization. Typically, this means that there are, in the human domain, no fixed objects with well-defined characteristics for scientists to (try to) represent. In its more familiar forms, this point is, of course, an obvious development of Dilthey's observations about the 'hermeneutic circle.' It has been much emphasized by Derrida (1978) and others of his school. Specifically, if interpretation takes place against and in terms of a background that is not 'given' but must itself be an object of interpretation, then every interpretation has the form, not of an objective (if possibly incorrect) description, but, rather, of a (performative) proposal to see the situation in one of the many ways in which it could (as) legitimately be seen. There is on this account insufficient interpretive stability to warrant attributions of objectivity.

Complexity

The economist Hayek (1978: p. 26f.) had already emphasized a kind of complexity that human studies practitioners must try to deal with. Such 'organized complexity' resists reduction either to deterministic or to statistical models that might be appropriated from the 'hard' sciences. The behavior of a social aggregate often cannot, in other words, be reduced to the sum

or product of the behavior of its individual parts, nor can it be adequately understood by characterizing its statistical properties (as the behavior of an aggregate of gas molecules might be understood, for instance). Later theorists (see Mitchell, 2009 for a good summary) have emphasized a kind of complexity that arises when phenomena are subject to multiple causal factors which interact in a particular way, so that, for example, the *relationship* of two variables contributing to the phenomena itself varies according to the value of a third variable. This results (Kauffman, 1993) in a 'rugged landscape' of possibilities for understanding these phenomena … one which it is not easy to explore in a systematic way and in which it may not be possible to identify a best account of the phenomena.

Notice, furthermore, that there may be moral and prudential (as well as practical) reasons for refusing to reduce this complexity in ways standard in the 'hard' sciences, i.e., by 'experimentalizing' it. So, while scientists might be able to 'standardize' individual agents in an experimental setting so that their interactions *there* can be understood deterministically or statistically, there are moral objections to exporting these conditions to *extra*-experimental settings. Indeed, there may be prudential reasons for not using these techniques of standardization in 'naturalistic' settings – as is implied, of course, by Hayek's own analysis of the market. In particular, adequate functioning of a complexly organized whole may depend precisely on its individual elements *not* being standardized. In either case, there are thus limits to the objectivity (actually the 'ecological validity') of the results that might be obtained in laboratory settings.

Recent advances in 'generative social science' (Epstein, 2006) show, however, how complexity of this kind can be handled effectively, so long, of course, as the prediction or explanation of the behavior of individual social agents is not sought.

Interim Conclusion

All these impediments manifest themselves in an oft-expressed concern: There is often, especially compared with paradigm 'hard' sciences, a lack of progress in human studies. In particular, multiple and opposed paradigms persist in human studies, especially in any area of investigation which is likely to be of broadly 'political' interest and concern. As Geertz (1993: p. 4) has said, "calls for 'a general theory' of just about anything social sound increasingly hollow, and claims to have one megalomanic. Whether this is because it is too soon to hope for unified science or too late to believe in it is, I suppose, debatable. But it has never seemed further away, harder to imagine, or less certainly desirable than it does now."

Notwithstanding these concerns, progress in the admittedly 'local' understanding of trends and patterns has been noted and this is of some significance, both in relation to the aspirations to scientificity of the social studies disciplines and in relation to their efficacy in connection with policy development.

Alternative Conceptions of Human Studies

It may not make sense to compare sociology and psychology to the 'hard' sciences. How, then, could they otherwise be conceptualized … and hence institutionalized? There are a number of possibilities. (Manicas's cautionary note still applies, of course; if 'science' isn't a natural kind, then no more is 'literature' or any of the other disciplines with which human studies might be compared.)

Literature

If human studies cannot properly be compared to the 'hard' sciences, perhaps a comparison with literature and other forms of potentially edifying narrative or practical discourses is more appropriate. This, certainly, is the opinion of a wide range of late-twentieth century theorists, including Geertz, Charles Taylor, Gadamer, and others. Geertz, for instance, advocates (1993: p. 6) that we "turn from trying to explain social phenomena by weaving them into grand textures of cause and effect to trying to explain them by placing them in local frames of awareness …." Of course, it might seem, to practitioners, that such a heuristic reorientation (see Section Heuristically) would reduce the likelihood that human studies might have significant institutional influence (see Section Institutionally). However, it needs to be borne in mind that the institutional influence of sociology and psychology is rather patchy (this is made clear in utilization studies), and that literature still forms the basis for highly influential mass-media representations and analyses of the human situation.

Another related possibility is this. While sociology and psychology do not or cannot provide an objective account of human phenomena at the level of individual behavior, they can and do provide a variety of potentially important *perspectives* on these phenomena, and thus enable human beings to orient themselves more productively to them, especially by giving them frameworks for understanding these phenomena. In this vein, Rorty (1982: p. 247) draws a contrast between scientistic goals of prediction and control, on the one hand, and, on the other hand, practical goals of developing "descriptions which help one decide what to do." (With a particular political twist, this seems to have been Leo Strauss's approach (1989) too.) Here, of course, theories that explain or predict trends and patterns can play a significant role, as 'deciding what to do' is often a matter of deciding, not what an individual will do, but, rather, what a society ought to do about, precisely, trends and patterns – for example, the reduction, in the aggregate, of some undesirable behavior. Of course, since deciding what to do depends on values and other normative elements, and since there is widespread and apparently irreducible diversity in relation to these elements, the kind of 'practical knowledge' that nonscientistic forms of psychology and sociology might contribute to will not itself satisfy the most demanding requirements of objectivity, though this might well be on account of the difficulties of moral reasoning, not the difficulties of social studies enquiries.

Critique

There is a subtle difference, but an important one between the view that human studies offer edifying perspectives on or frameworks for the interpretation of human phenomena (see Section Literature) and the view that they offer a basis for critique and the advocacy of change. In the latter half of the

twentieth century, critical theorists (e.g., Habermas), genealogists (e.g., Foucault), feminists, and advocates for other marginalized groups (see Seidman, 1994) proposed and in some cases made progress in achieving a 'takeover' of human studies activities and institutions. Across this spectrum, techniques that have some claim to being 'antiscientific' (Foucault, 1980: p. 83) are widely employed. In particular, practitioners of critique shift the focus from showing how what is, socially, an intelligible consequence of its causal antecedents to showing how what is, socially, represents the highly contingent realization of practices and structures to which there are clear, achievable, and desirable alternatives. As Foucault says (Rabinow, 1984: p. 46): "[T]his critique will be genealogical in the sense that it will not deduce from the form of what we are, what is impossible for us to do and to know; but it will separate out, from the contingency that has made us what we are, the possibility of no longer being, doing, thinking, what we are, do, or think. It is not seeking to make possible a metaphysics that has finally become a science; it is seeking to give new impetus, as far and wide as possible, to the undefined work of freedom." It is not, then, a matter of objective representation, but, rather, of politically effective analysis of the possibilities for change. (This is, of course, an extension of Karl Marx's 11th thesis on Feuerbach: "Philosophers have only *interpreted* the world in various ways; the point is to *change* it.") Even in this context, of course, knowledge about the forces and factors sitting underneath trend and pattern data will be valuable.

Disciplines or Ideologies

There are (see Section Complexity) moral and prudential disincentives to investigating human phenomena experimentally and, a fortiori, to 'exporting' into 'naturalistic' settings those conditions in which objective, reproducible experimental effects have been obtained. This has not, of course, stopped such things from happening and, indeed, it is the main conclusion of Foucault and others of his school that human studies have played a key role in this process, and, in particular, that they have contributed to the production of a 'disciplinary society' in which individuals are governed via their consent, i.e., through the ways in which they are made into 'subjects.' Although Jürgen Habermas disputed much that Foucault wrote and did, he was at one with him on this point. Habermas (1994: p. 54) says, for instance: "It is no accident that these sciences, especially clinical psychology, but also pedagogy, sociology, political science, and cultural anthropology, can, as it were, frictionlessly intermesh in the overall technology of power that finds its architectural expression in the closed institution. They are translated into therapies and social techniques, and so form the most effective medium of the new, disciplinary violence that dominates modernity." (See Hoffmann, 2003 for the disciplinary use of social studies in the interwar Soviet Union.)

That human studies are 'disciplines' is one way of capturing their importance and their negative impact on the lives of ordinary people; that they have functioned ideologically is another way of making this point. Perhaps the most important issue here is the way in which human studies have been recruited by other powerful institutions to serve the specifically political interests of those institutions while seeming to provide a nonpolitical analysis, a value-neutral account of contemporary social conditions. The idea of expertise has played an important role in this development. Insofar as social and psychic problems can be modeled on purely technical problems, solutions can be offered and consumed on a purely technical basis, and the reality of their dependence on fundamentally political matters can remain inaccessible to consciousness.

Conclusion

Should human studies plausibly aspire to scientific status? This remains questionable, as it has long been. There are a variety of legitimate enterprises, including edification and critique which may be more important, for society, than explanation and prediction on an objective basis. Of course, these enterprises, whatever their status, may themselves be informed by properly conducted empirical enquiries. Can they realistically aspire to such a status? This depends very much on where the bar is set. If we look to social studies for the explanation and prediction of individual events in the social world, they will not, typically, satisfy the highest methodological demands that might be satisfied, at least under laboratory conditions, by the paradigm 'hard' sciences. On the other hand, there are other aspirations and, perhaps Rorty (see Section Literature) is right to suggest that human studies have aspired to too much, that their two main goals are disjoint and hence both cannot be achieved under the same methodological or institutional auspices. In this case, practitioners would perhaps be wise to disentangle their various objectives, and adjust their 'aspiration levels' (Simon, 1996: p. 30) to more realistic goals. Certainly, the analysis of trend and pattern data and its generative derivation using agent-based modeling techniques shows a middle way for those social studies which aspire to scientific status. There are methodologically sound 'local' patterns and trends that appear to be well understood, either through regression over variables or by computer simulations. Such an approach is, in fact, consistent with the even more radical adjustment of aspirations and disciplinary cultures. Toulmin calls for when he says (1992: p. 193) that "The task is not to build new, more comprehensive systems of theory with universal and timeless relevance, but to limit the scope of even the best-framed theories, and fight the intellectual reductionism that became entrenched during the ascendancy of rationalism … [thus reinstating] respect for the pragmatic methods appropriate in dealing with concrete human problems."

Social Scientists as Experts and Public Intellectuals

Stephen P Turner, University of South Florida, Tampa, FL, USA

Abstract

Experts and intellectuals in the social sciences have a long history of relating to the state and the public. These relations vary in kind from those based on technical knowledge applied to policy to cults to social scientists in organic relations to social movements to organized attempts to develop public policy guided by social science knowledge. The most successful early attempts were cameralism and official statistics, but intellectuals like John Stuart Mill also reached a wide public audience in the nineteenth century. In the late nineteenth century, social reform movements claimed expert knowledge. As the social sciences entered the university, however, the forms of influence changed. Under the influence of the Rockefeller philanthropies, social science became more 'realistic' and the emphasis shifted to creating professions dependent on academic knowledge and certification. Think tanks and other forms of knowledge intervention developed which relied on academic social science. Public intellectuals, however, speaking not to professions or bureaucrats, remained important.

People we now think of as social scientists and psychologists were 'experts' and sought to influence public policy as well as public discussion and personal behavior long before 'social science' was itself conceived of as an academic study. In many fields of the present social and behavioral sciences, practice preceded and formed the basis for the creation of a body of theoretical or systematic empirical knowledge. This is true to a significant extent of science generally, as writers on the origins of science in the 1930s, such as J.G. Crowther and Lancelot Hogben, emphasized. But the social sciences exhibit some distinctive patterns, and vary considerably depending especially on the way in which they relate to official bodies and publics. These relations have changed over time, especially with the disciplinarization of the social sciences, the support of foundations, and the present situation, in which there is a substantial governmental investment and use of social science. The changes also reflect changes in the state, in forms of social provision, and in the means of state economic intervention.

In understanding the role of social scientists as experts and public intellectuals, it is important to understand the ways in which this role has both developed and varied under these different circumstances. There are three major vectors relevant to understanding this role: the question of who pays for knowledge and how it is paid; the audience for knowledge; and the bureaucratic and political structures and traditions within which knowledge is applied. Audiences vary from the public to private professional practitioners (such as physicians and lawyers) to civil servants in expertized bureaucracies, the purposes that experts have in speaking to them, and the kind of knowledge at stake, varies as well. The purposes may range from influencing legislation or policy to influencing administrative decisions, to influencing personal behavior, to providing intellectual orientations relevant to political issues, and the content may vary from practical advice to abstract theory to petition signing in support of causes.

Expertise: A Typology

Experts may be categorized according to the way in which they relate to the public and public bodies. One kind of expertise, which other forms emulate, is modeled on technical knowledge, and specifically limits the role of the expert to technical advice based on empirical research. This kind of expertise is normally rooted in academic training and a community of self-defined and selected experts, and is made accessible to users, who support research related to their own aims. It gains its legitimacy from being publicly recognized as genuine expertise. Technical expertise of this kind is ordinarily self-limited to the specific domains of technical knowledge. In practice, this kind of knowledge is insufficient in itself to inform public policy or public opinion, but it can constrain the claims of other kinds of experts. However, the line between technical expertise and expertise beyond the narrow confines of what is established technically is often vague, and those who possess technical knowledge often claim more than is justified.

Expertise could be said to differ from scientific knowledge proper in that it represents the state of knowledge at a particular time, and is not limited to fully developed or tested theories or facts accepted as textbook knowledge by the academic community. In this respect, expertise resembles meta-analysis. Experts are normally expected to be aware of conflicting claims and the range of relevant knowledge and opinion on the topic in question, and to be able to aggregate this knowledge and make judgments about the methodological adequacy, significance, and relevance of various knowledge claims to present policy questions. But they are not expected to fully agree on their advice and conclusions, which may involve nontechnical elements, of values or policy considerations that are contested, often by other experts.

Within this very broad definition, several major variants may be distinguished. One model of expertise involves the direct appeal to ordinary citizens and persons on the basis of claims of special access to relevant knowledge with some sort of certification or sanction of the status of the expert in a community of experts or specialists that recognizes their expertise. The expert speaking directly to the public on the basis of specialized knowledge is, in contrast, speaking for specialists whose knowledge is being publicly represented by the expert, who is speaking for this community. This kind of expert appeal plays a role in all the social and behavioral sciences, but is far more developed in such fields as psychology and child

psychology than others. In this model, the audience of the expert is a body of consumers who use this knowledge for their own purposes, and judge it largely on grounds of its efficacy for them. In economics, the body of users is persons interested in issues of finance and policy who are themselves relatively sophisticated, though not expert in the same sense. 'Public intellectuals' are a variant of this category. They are taken to possess specialized knowledge, but they speak on issues that go beyond that specialized knowledge, and attempt to direct or influence public opinion in domains beyond the narrow domain in which they secured their professional reputation.

A second type of expertise is directed at official bodies from outside. An example of this is the field of international relations: here academic experts, with access to a body both of theory and empirical and historical material, attempt to influence the conduct of diplomats and government bodies. In this field, depending on the national traditions governing state bureaucracies, there is sometimes a 'revolving door' between academia and offices. However, strong civil service traditions, in general, tend to exclude 'outside' expertise. Though there are exceptions to this rule, there are significant local differences in the ways in which experts relate to bureaucracies.

An important particular form of this relation is expertized bureaucracies: cases in which academic qualifications or background become conditions for official appointment and in which advancement depends on continued engagement with professional associations. A complex variant of this relation was promoted by the Rockefeller philanthropies. The Rockefeller model, based on the experience of reforming American medicine, involved multiple elements: the professionalization of domains of activity, such as public administration in the United States, and involved the creation of degree programs, institutes, bodies of academic research, and intermediate institutions for continuing education and for the promotion of new expert knowledge to audiences of officials. This kind of expertise is not directed at 'the public' and indeed is claimed to be form of technical knowledge, but it is also created to be applied. The most developed social science application of this model is the field of public administration in the United States.

A variant of this use of expertise is associated with the New Public Management movement of the 1980s, which outsourced work requiring specialized expertise to consultants. This was motivated in part by efforts at reducing the size and personnel costs of permanent bureaucracies, but also was a response to long-standing issues that arose from the conflict between the hierarchical career structure and generalist character of civil service knowledge and the specialized technical knowledge relevant to specific decisions. In the British case, this conflict initially arose in connection with the siting of telegraph lines, and the anomaly of junior technical officials giving instructions to senior (but nontechnical generalist) officials.

Another type of expertise is recognized primarily by a specific audience, but not generally recognized or widely dismissed. The extreme form of this is the expertise recognized within a cult. This type of expertise shades into cases where there are groups, including specialists, that accept the claims of expertise, yet the claims are contested in the public domain. This type of contested expertise has a significant role in the history of the social sciences. Psychoanalysis and Marxism are examples, but there are many more: Auguste Comte's positivism was turned into a literal cult, and such movements as Reichian analysis were cultlike as well. But there is a similarity as well to conscious attempts to develop ideological or policy-oriented points of view on the basis of social science. Austrian economics and the Frankfurt School might be examples of this.

A third kind of expertise is associated with social movements and reform. The movements are independent of the state and aim at producing state action, normally legislative or regulatory change, and rely on expertise claims together with political pressure and organized public support. This kind of expert relationship has a large significance in the history of the social sciences in the predisciplinary period. During the 'disciplinary' period, this kind of relationship persisted, but conflicted with ideas about value-free science in fields like sociology. A new form of this relation appeared in the relation between women's studies and feminism, and is exemplified presently in the idea of 'public sociology' as involving an organic relation between sociologists and particular social movements.

This kind of expertise differs from the cult form in that cult forms generally demand exclusive loyalty and develop factions, whereas social reform movements are normally nonexclusive, allow for multiple involvement in different causes by the same persons, and tend to proliferate aims rather than factionalize, reflecting the fact that they are goal-oriented rather than ideological in character. The differences are not absolute, and in certain periods reform movements were colonized as fronts for ideological movements. Typically, however, reform movements have attempted to cooperate and coordinate with one another.

These different forms of expertise operate through distinctive institutional structures, and have distinctive products. Among the most important forms are what in science studies are known as 'boundary objects': reports or other accessible sources of knowledge that purport to represent the policy relevant facts on a particular topic. These are often produced by knowledge-intensive institutions, such as the World Bank, which employ large numbers of experts and seek to influence governments through the diffusion of expert consensuses. Expertise is disseminated in many other ways, however, from journalism and television appearances to textbooks directed at persons training for expertized bureaucracies. Among the characteristic institutional structures are think tanks, commissions, and panels.

Expertise and Public Intellectuals in the Predisciplinary Period

The cameralists, the political arithmeticians, and various political philosophers are acknowledged precursors and models for what became social science. These intellectuals prior to university 'social science' were paid in various ways, and their writings had public audiences. Niccolo Machiavelli and Thomas Hobbes, for example, were courtiers, advisors to powerful families whose public writings followed and were based on their advice and experience. The cameralists, who were administrators for the absolutist states of central Europe, in contrast, developed an intellectual tradition and interacted

with one another, but were not concerned with persuading the public. Instead, they represent a continuous tradition of administrative expertise based on a theory of statecraft: a doctrine of *Polizeiwissenschaft*, according to which the ruler of a principality enhances his own power by improving the economic and moral life of his subjects through mercantilist regulation and the paternalistic use of state administrative power through magistrates to improve morality. This was the beginning of academic social science: many of the cameralists were university professors who simultaneously held administrative positions, a pattern that persisted in the German-speaking world well into the nineteenth century.

These two patterns, the public and the bureaucratic, developed in different directions. In the eighteenth century, Hume and Adam Smith were supported by wealthy patrons, though they were not entirely dependent on them. Smith became a professor of moral science at the University of Edinburgh. Hume's history of England was a best seller. The Encyclopediasts, in France, also derived income from literary projects. This was the beginning of a period in which the educated public was a paying audience. 'Social science' at this stage was a part of a much larger body of successful literary publishing for this audience, and beneficiary of this growing and increasingly prosperous group.

It was not until the eighteenth century and the development of a significant book market that enlightenment thinkers such as Voltaire, Diderot, and Rousseau were able to support themselves through literature, but they could do so only barely and with aid. The famous Encyclopedia on which Diderot collaborated sold 25 000 copies; the income from this and his other writing was not enough to support him, but he was helped by Catherine of Russia, who bought his library and paid him a pension. Edward Gibbon and Hume were also supported by aristocrats.

In the nineteenth century, John Stuart Mill, who has been described as the greatest public intellectual of the last two centuries, worked for the East India company and derived income from his writings as well, especially his *System of Logic* (1882), which outlined his account of the methodology of social science, including his conclusion that social science, together with the utilitarian principle, would provide a complete policy science. He was part of a current of liberal thinkers, including Harriet Martineau, Walter Bagehot, and Herbert Spencer, who wrote for the market. The latter two got their start in financial journalism, which has ever since been a major conduit for communicating expertise, especially in economics, to the 'public,' and was the first domain in which experts could support themselves through writing.

These writers had a complex relation to the public and the literary market. Their most important intellectual works were not the source of their income. Most of them needed an inheritance to enable them to commit time to writing social science: Karl Marx was subsidized by Friedrich Engels, Comte by Mill. Spencer and Henry Buckle, author of the astonishingly successful *History of Civilization in England* (1864), inherited wealth that enabled them to turn to social science. It is a small irony that the great exponents of liberalism were unable to survive in the market. Nevertheless, the fact that they did derive income from the public literary market, and often through journalism, meant that they were subject of the discipline of communicating to this market, and this was reflected in their writings on social science, which were accessible rather than scholarly. For this reason, many of their works are still read today, in contrast to the works of the early academic social scientists.

The bureaucratic tradition, which was initially limited to the rationalizing absolutist states that were former parts of the Holy Roman Empire, developed into two strands: *Nationalökonomie*, a mercantilist state-oriented economic tradition, and statistics, which altered its original meaning of being concerned with the properties of states as part of *Staatswissenschaft* to the collection and governmental use of statistical data. The classic expression of the statistical office was the Royal Prussian Statistical Bureau, founded in 1805, which produced a large number of reports. Almost all of the important German contributors to statistics before 1860 were professors who had significant practical experience and held at some point, or at the same time, official positions in bureaus of statistics (Lindenfeld, 1997). In Britain, in contrast, social statistics was associated with reform movements and official bureaus and the statistical society grew out of local private statistical societies with a strong social reform interest, while academic statistics developed in connection with agricultural research. The leading figure of early social statistics, William Farr, who worked at the General Register Office for England and Wales, found it impossible to get academic legitimation for the field, but was nevertheless enormously influential as a sanitation reformer.

Statistics emerged as the best-organized social science by the middle of the nineteenth century, with international statistical congresses and a section of the British Association for the Advancement of Science. Statistics was understood not merely as a mathematical field, but as a science of humanity. The study of suicide was especially influential on public discussion, producing the 'suicide problem.' In the latter part of the century, the focus shifted to labor statistics, and national labor statistics bureaus, which rapidly developed during this period, exchanged publications and promoted information on the cooperative and profit-sharing movements. Statistical reports on wages and policy were widely discussed and debated, particularly in relation to the statistical phenomenon of unemployment and issues over wages.

Cultlike groupings played an important role among the early nineteenth century precursors of social science. The followers of Saint-Simon constituted a kind of lifestyle cult, which included ceremonies, hierarchies, a form of religious mysticism, and a kind of church. August Comte, who had been a secretary to Saint-Simon himself, created a similar structure on the basis of his sociology, a religion of humanity with churches (and a factionalized movement) that lasted almost a century. It is a matter of controversy whether one should include such movements as Marxism and psychoanalysis in this category, but they exhibit some common features, notably factionalization. Their claims to expertise were not universally accepted, and they did not become, except in the case of Marxism in the Communist world, academically normalized, but they influenced, as positivism did, many people outside the cult. Similarly, Saint-Simonianism was a major source of French feminism, and Marx's father was a member of a Saint-Simonian reading group.

These movements shade into another important category: reform movements with intellectual leaders, or, in the language introduced by Antonio Gramsci, organic intellectuals, that is to say intellectuals who identify with and intend to express the thoughts and aspirations of a particular social group, such as a class. The nineteenth century produced a vast array of these reform movements, organized to educate, to influence legislation, and often to provide services, including expert advice. The topics ranged from household management and child-rearing to social and economic legislation and prison reform. Among the most intellectually fruitful of these movements were cooperativism, Fabianism, and Henry George's single tax movement, which stimulated discussions of land reform. In the United States, these movements produced such celebrities as Jane Addams, in Britain Beatrice and Sidney Webb. These movements promoted the entry of the social sciences into the university, and for a while maintained a close relation to the newly academicized fields, they eventually came into conflict with them, for reasons that will become clear shortly.

Transitions to Disciplinarity

The academicization of social science was uneven between countries and between disciplines, but for the most part rested on the promise that the development of academic expertise would produce practical results. Much of it built directly on social reform movements. Movements for such things as prison reform and the special treatment of juvenile offenders as well as the regulation of child labor were important elements of the American Social Science Association of the nineteenth century. This body, which had a British analogue, was the precursor to the disciplinary social science bodies that were founded in the United States and elsewhere around the beginning of the twentieth century. These associations promoted the idea that expert knowledge was needed in the operation of state institutions as well as the creation of university social science, and were typically supported by wealthy donors as well as membership fees.

The London School of Economics was a project of the Fabian society, and was needed because of the reluctance of the traditional universities to accept the social sciences. In France, sociology entered the university under the academic heading of pedagogy. Psychology entered under this heading in the United States. Aside from *Staatswissenschaft*, the field with the greatest initial success in entering academic life was German *Nationalekonomie*, which presented itself not as a pure science but as providing the basis and ideology for national economic policy and development. German economists exercised their expertise in various ways, for example, through commissions. Max Sering, Adolph Wagner, and others represented the dominant 'Socialists of the Chair,' and were organized in the *Verein für Sozialpolitik*, which produced policy advice and studies. The problem of agricultural policy and rural life was common to all major countries, and produced a variety of responses in the form of commissions and research projects, as well as policy recommendations. These provided both a basis and transitional stage to the creation of academic policy-oriented fields of agricultural economic and rural sociology, and embedded this form of expertise in agricultural bureaucracies.

The transitional period in which there were a large number of nonacademic expert organizations and a relatively small academic presence of social science varied from country to country. In the United States, there was a vigorous reform community, especially in New York City, that paralleled the Fabian society with which academic social science cooperated, for example, by providing graduates and by participating in public educational efforts (Recchiuti, 2006). These organizations were oriented to the task of public education, and created many novel forms. By the early twentieth century, there were, for example, 'Social Museums' in Paris, Budapest, Munich, Bremen, Charlottenburg, and Frankfurt. In addition, these institutions typically held lecture series. In Britain, Patrick Geddes created 'Outlook Tower' in Edinburgh to educate about the social world; he also put on masques–costume dramas illustrating human progress. At LePlay House in London, the Sociological Society held lectures and exhibited the results of social surveys. In the United States, Harvard's Emerson Hall housed the Peabody Social Museum, and temporary museum-like displays were created for the major social surveys, notably the Pittsburgh and Springfield surveys. There were also social institutes of various kinds in Belgium, Denmark, and Sweden, and a large number of 'societies' with specific problem orientations in Germany.

There were also innovative expert organizational forms, such as the Municipal Research Bureaus in the United States, which supplied objective statistical information on issues related to urban governance, under an ideology of efficiency that had a large international following. But in the 1920s, the reform community was losing direction, having achieved many of its most popular practical goals, and was suffering from its association with prohibition and the temperance movement, one of the most powerful and visible reform movements, which had a vast international following.

The connections were broken in part because of the efforts of the Rockefeller philanthropies, which engaged in massive support for the social sciences. In Europe, the support was largely an effort to better establish the social sciences, but preference was given to work that was 'realistic.' In the United States, the aims were more precise. The aim of the foundations was to improve on the social reform movements of the nineteenth century and the efforts of such reformist foundations as the Russell Sage foundation, which provided reform expertise in a range of areas, by basing them on better data and greater objectivity. The strategy was to first promote more objective social science, then for it to be applied to social and economic problems. In this respect, they were largely disappointed: objective social science did not turn out to be a panacea. Nevertheless, such works as William F. Ogburn's massive *Recent Social Trends* project (1933) did establish objective social science in the public mind as a distinctive form of expert knowledge.

During the 1930s, Franklin Roosevelt assembled a team of expert advisors, known as the 'Brain Trust,' mostly from law schools, to help formulate policy. Among them, however, were academic social scientists, such as Rexford Tugwell, an agricultural economist and advocate of planning, which was a key issue of the decade. A similar role was played by John Maynard Keynes in Britain, who advised the cabinet directly, and in Italy by 'Mussolini's statistician,' Corrado Gini. These prominent figures legitimated the idea of academic expert advisors. In the United States, economic advice was formalized in the Council

of Economic Advisors, and academically trained economists dominated the boards of the Federal Reserve Banks.

The academic social sciences turned away from the reformers in the 1920s and 1930s in the United States, and a model of the role of the social scientific expert that limited the expert to the factual emerged out of this reorientation. One motivation was the experience of the First World War, in which academics in all countries provided intellectual support for their side. In the victorious countries, this produced brutal recriminations after the war, exemplified by Julien Benda's *The Treason of the Intellectuals* (1928[1927]). In the United States, the psychologist James McKeen Cattell was dismissed for his public opposition to the draft and became a hero in the cause of academic freedom, which led to resignations by other prominent Columbia faculty. The propaganda operations of the Office of War Information were retrospectively vilified, and a wave of historical revisionism challenged the assignment of war guilt to the Germans. In Germany itself, there was a broad debate, occasioned in part by Max Weber's address *Science as a Vocation* (2012[1919]), on whether professors should attempt to provide valid worldviews.

This was an important part of the background to developments in which social scientists, especially in the early-and midtwentieth century, sought to free themselves of the accusation that they were merely ideologists or apologists for the state or the established order by identifying a domain of 'science' or expertise that was entirely factual or at least neutral. This claim also facilitated the entry of social sciences into the university as scholarly disciplines, an entry which in many countries was very late and often controversial. Initially, this more limited conception was associated with fact-mongering and criticized as such, but later was given a more coherent defense by George Lundberg in *Can Science Save Us?* (1947) in terms of a version of the ideal of value-free social science, which associated democratic decision making with questions of ends, and made social science into the servant of decision making by supplying the factual basis on which to choose means – a way of making the distinction that recalled Mill and Weber, but could serve as a practical professional ideal for secure academic disciplines. This way of separating science from politics was criticized in such polemics as Robert S. Lynd's *Knowledge for What?* (1939) and Howard S. Becker's speech *Whose Side are We On?* (1967), and by 1960s radicals.

These self-limitations, however, were influential primarily in disciplines formerly associated with reformism, such as sociology, and were less important in such fields as economics, which recognized a normative as well as a positive aspect of disciplinary knowledge, and psychology, which had a clinical side. Management theory, which produced both a practical discipline and one of the most prominent public intellectuals, Peter Drucker, always had a normative or best practices component. International relations as a field has, especially in the United States, been associated with advising, and with powerful political positions in the diplomatic or national security system.

National Differences

Much of the literature on both expertise and public intellectuals focuses on national differences. In Raymond Aron's ironic phrase, France 'passes as the paradise of the intellectuals.' French intellectuals, since the Dreyfusards, are taken to be respected and influential, especially for their political pronouncements, and their collective approval or disapproval, classically in the form of petitions, has been the characteristic mode of action. The French intellectuals of the middle twentieth century are commonly taken as the high water mark of the influence of intellectuals, and this included some social scientists, such as Georges Friedmann and Aron himself, though it is normally philosophers and literary figures, such as Sartre and Camus, who are now regarded as paradigmatic public intellectuals.

This is quite different from possessing influence over ministries as experts, or of exercising control over the professional status and reputation of bureaucrats through professional organizations dominated by academics, or even of being party intellectuals with influence over party members. It has also been observed that the public role of French intellectuals reflects in part the limited possibilities of more direct impact on political and administrative decision making. When French intellectuals are driven to public commentary on politics, the commentary is especially on the morality of political decisions. This in turn points to the more general issue of the ways in which political and administrative structures as well as the receptivity of the relevant publics determines the possible roles of experts.

The case of international relations exemplifies the general principle that the role of social science experts is limited by the bureaucratic structures with which the social scientist interacts: In the United States, there is a 'revolving door' between government and academia and think tanks, while in Central Europe the civil servant tradition is strong, and there is normally very little direct influence on policy making by academic experts. However, there is a larger role of intellectuals in providing political orientation. Britain, which had a particularly insular and strong civil service tradition hostile to social science expertise, had two of the most influential of all social scientists: Keynes in economic policy, whose advice went directly to the cabinet, and R.H. Tawney, who laid the intellectual and moral foundations for the welfare state through his writings and also his engagement with the Christian social and workingmen's organizations. In Germany, intellectuals are widely discussed in newspapers, and are expected to have political viewpoints and to provide worldview-like intellectual orientation to political matters, though are not expected to engage in details of ministerial policy, and normally do not, as in France, engage directly in specifically 'moral' leadership.

Other national differences have significant effects for the way in which intellectuals in general and social scientists in particular interact with the public and with decision makers. The tax law governing foundations in the United States, together with a tradition of private sponsorship, creates a situation in which nominally nonpartisan organizations can seek to influence policy by studies and reports, or by creating an intellectual environment. 'Think tanks' represent a variation on this model. They are funded in order to provide intellectual substance to a point of view or policy orientation favored by the funders. They are normally not associated directly with a social movement, but do seek to influence policy and policy discussions. The private Mt Pelerin Society did this on an international level by developing promarket intellectual orientations to public policy issues in the postwar period, in

response to the intellectual dominance of planning-oriented intellectuals in the 1930s (Mirowski and Plehwe, 2009). Differing legal definitions of freedom of speech have effects as well. Political parties in Europe involve paid memberships, and generally exclude large donors, and political messages to the public are driven by parties, and think tanks normally receive some government support, whereas in the United States, they are normally privately funded.

Social Simulation: Computational Models

Michael W Macy, Cornell University, Ithaca, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article compares computational and mathematical models and reviews three phases in social simulation - dynamical systems, microsimulation, and agent-based modeling. The latter can be used to identify possible micro-level mechanisms that might account for puzzling empirical patterns and to identify population-level implications of a set of behavioral and structural assumptions about individual interaction. Classic examples include Schelling's model of residential segregation and Axelrod's model of the evolution of cooperation. The article concludes with an assessment of important criticisms.

Computational social simulation involves the use of computer algorithms to model social processes. These algorithms require greater precision and logical rigor than natural language yet lack the generality of closed-form mathematical equations. The use of computer simulation by social scientists has increased in recent years, due to growing interest in modeling nonlinear dynamical processes using graphical interfaces that allow highly intuitive visual representations of the results. Social simulation has also undergone a qualitative change as the emphasis has shifted from prediction to explanation.

This article reviews three 'waves' of innovation: dynamical systems, *microsimulation*, and adaptive agent models (Gilbert and Troitzsch, 1999). These three approaches will be summarized as follows:

1. 1960s: Dynamical systems simulations were empirically grounded, inductive, holistic, and functionalistic.
2. 1970s: Microsimulation introduced the use of individuals as the units of analysis but retained the earlier emphasis on empirically based macrolevel prediction.
3. 1980s: Adaptive agent models revolutionized computational social science by simulating actors not factors (system attributes). These 'bottom-up' models explored interactions among purposive decision makers.

Although these three 'waves' overlap (e.g., economists continue to use holistic simulation of productive factors, microsimulation was invented in 1957, and nascent agent-based models appeared in the late 1960s), most of the recent excitement in computational modeling in the social and behavioral sciences has centered on agent-based simulation. So too has much of the controversy.

Dynamical Systems

The first wave of computer simulations in social science occurred in the 1960s (Cyert and March 1963). These studies used computers to simulate dynamical systems, such as control and feedback processes in organizations, industries, cities, and even global populations. The models typically consist of sets of differential equations that describe changes in system attributes as a function of other systemic changes. Applications included the flow of raw materials in a factory, inventory control in a warehouse, urban traffic, military supply lines, demographic changes in a world system, and ecological limits to growth (Forrester, 1971; Meadows et al., 1974).

Models of dynamical systems are functional and holistic (Gilbert and Troitzsch, 1999). *Functional* means that theoretical interest centers on system *equilibrium* or balance among interdependent input–output units. *Holistic* means that the system is modeled as an irreducible and indivisible entity. Although these models allow nested organizational levels, at any given level, they assume that sets of related attributes (such as economic growth, suburban migration, and traffic congestion) are causally linked at the aggregate level.

Microsimulation

The second wave of computational modeling in the social sciences developed in the late 1970s. Known as microsimulation, it represents the first step in the progression from factors to actors. In striking contrast to the earlier holistic approach,

> microsimulation is a 'bottom-up' strategy for modeling the interacting behavior of decision-makers (such as individuals, families, and firms) within a larger system. This modeling strategy utilizes data on representative samples of decision-makers, along with equations and algorithms representing behavioral processes, to simulate the evolution through time of each decision-maker, and hence of the entire population of decision-makers. (Caldwell, 1997)

For example, Caldwell and Keister use CORSIM, a large-scale dynamic microsimulation model of the US population of individuals and families, to integrate individual and family level wealth behavior with aggregate-level stratification outcomes. This microanalytic approach allows researchers to avoid a serious limitation in the earlier generation of simulations: population homogeneity. For example, the relationship between wealth and age may not be uniform across ethnic or religious subcultures, geographic regions, or birth cohorts. Complex interactions across subpopulations are lost when the focus is on the correlation among aggregate factors. This precludes the ability to predict the effects of policy changes that impact only certain groups.

Microsimulation solves this problem by modeling individual-level attributes as well as population-level vectors.

The database structure consists of individual records for a representative sample of a population, with a set of individual attributes measured at multiple points in time. These individuals are then 'aged' by updating their attributes, based on a set of empirically derived state-transition probabilities (e.g., an individual's move from work to retirement at age 65). These probabilities are then used to predict new states of each individual, and these are then aggregated to make population projections.

Agent-Based Models: The Third Wave

The third wave, agent-based models, attracted widespread interest beginning in the 1980s. These models extend the microanalytical approach by deriving global states from individual *behaviors*, not individual attributes. In microsimulation models, individuals are inert in two ways: (1) the state of an individual is a numerical function of other traits and (2) individuals do not interact (Gilbert and Troitzsch, 1999: p. 8). Agent-based models assume an individual has intentions or goals and makes choices that affect other agents whose choices in turn affect that individual. These models impose four key assumptions:

1. Agents interact with little or no central authority or direction. Global patterns emerge from the bottom up, determined not by a centralized authority but by local interactions among autonomous decision makers.
2. Decision makers are adaptive rather than optimizing, with decisions based on heuristics, not on calculations of the most efficient action (Holland, 1995: p. 43). These heuristics are implemented as logical rules and correspond to individual habits, social norms, organizational protocols, rituals, conventions, customs, and bureaucratic routines. They evolve at two levels, the individual and the population. Individual learning alters the probability distribution of rules competing for attention, through processes like reinforcement, Bayesian updating, or the backpropagation of error in artificial neural networks. Population learning alters the frequency distribution of rules competing for reproduction through processes of selection, imitation, and social influence (Latané, 1996). Genetic algorithms (Holland, 1995) are widely used to model adaptation at the population level.
3. Decision makers are strategically interdependent. Strategic interdependence means that the consequences of each agent's decisions depend in part on the choices of others. When strategically interdependent agents are also adaptive, the focal agent's decisions influence the behavior of other agents who in turn influence the focal agent, generating a complex adaptive system (Holland, 1995: p. 10).
4. Agents interact locally. Computational models of dynamical systems, as well as game-theoretic models of strategic interdependence, typically assume a population in which each individual is connected either to everyone or to a randomly distributed subset. Although there are few, if any, historical examples of social networks that are either random or fully connected, this assumption is nevertheless appealing because it allows analysts to derive closed form mathematical solutions. The few models that have incorporated local structure have assumed that social ties are exogenously determined and do not change over time.

Agent-based models have for the first time opened up applications of computational modeling to the study of social life embedded in dynamic networks.

Examples

Thomas Schelling's (1971) 'neighborhood segregation' model was one of the earliest agent-based social simulations. Schelling used an impressively simple and elegant model to address a perplexing empirical puzzle. The 1964 Fair Housing Act outlawed racial discrimination in the residential market, and surveys since that time show a progressive increase in tolerance of outgroup neighbors. Yet urban residential segregation has hardly changed. Schelling's model provides a compelling explanation. Consider a residential area that is highly segregated, such that the number of neighbors with different cultural markers (such as ethnicity) is at a minimum. If the aggregate pattern were assumed to reflect the attitudes of the constituent individuals, one might conclude from the distribution that the population was highly parochial and intolerant of diversity. Yet Schelling's simulation shows that this need not be the case. His 'tipping' model shows that highly segregated neighborhoods can form even in a population that tolerates diversity. The aggregate pattern of segregation is an emergent property that does not reflect the underlying attitudes of the constituent individuals.

Another classic is Axelrod's 1987 model of the evolution of cooperation, which addressed another empirical puzzle: how is it possible for cooperation to evolve, given the reproductive advantage to those who exploit the generosity of others? Axelrod used a simple agent-based model to study the viability of cooperation in a 'prisoner's dilemma,' a two-player game in which choices that are individually rational aggregate into collective outcomes that are suboptimal for both players. The results showed that strategies based on reciprocity (such as 'tit for tat') tend to be very successful. The secret of their success is that they perform well against copies of themselves without being vulnerable to predation. Axelrod showed how a simple rule of 'tit for tat' can gain a toehold even in a population of predators and go on to thrive.

Later Axelrod (1997) used computational models that couple homophily (likes attract) and social influence to explain the robustness of cultural diversity despite the relentless pressures of assimilation. If local similarity facilitates interaction, which in turn facilitates influence, it is indeed curious that the global outcome is diversity, not uniformity. The process resembles biological speciation in which initially similar organisms distributed over a large surface become sufficiently different from those in distant regions that they can no longer mate should they encounter one another through migration.

Although Axelrod characterized these models as 'evolutionary,' the agents were unable to learn or discover new strategies. Later models added the ability to learn new rules. The 'genetic algorithm' invented by John Holland is a simple

and elegant way to model strategies that can progressively improve performance by building on partial solutions. Each strategy consists of a string of symbols that code behavioral instructions, analogous to a chromosome containing multiple genes. The string's instructions affect the agent's reproductive fitness and hence the probability that the strategy will propagate. Propagation occurs when two or more mated strategies recombine. If different rules are each effective, but in different ways, recombination allows them to create an entirely new strategy that may integrate the best abilities of each 'parent' and thus eventually displace the parent rules in the population of strategies.

Agent-based models can implement adaptation at the individual level as well. While evolution alters the frequency distribution of strategies at the population level, learning alters the probability distribution of strategies within the choice set of an individual agent. For example, artificial neural networks are simple self-programmable devices that model agents who learn through reinforcement. Like genetic algorithms, neural nets have a biological analog, in this case, the nerve systems of living organisms. The device consists of a web of neuronlike units (or neurodes) that fire when triggered by impulses of sufficient strength, and in turn stimulate other units when fired. The magnitude of an impulse depends on the strength of the connection (or synapses) between the two neurodes. The network learns by modifying these path coefficients in response to environmental feedback about its performance. Neural nets have been used to study the evolution of religion (Bainbridge, 1995), kin altruism (Parisi et al., 1995), the emergence of status inequality (Vakas-Duong and Reilly, 1995), group dynamics (Nowak and Vallacher, 1997), and social deviance (Kitts et al., 1999).

Criticisms of Simulation

Agent-based simulations have been criticized as unrealistic, tautological, and unreliable.

1. Simulations, like mathematical models, tell us about a highly stylized and abstract world, not about the world in which we live. In particular, agent-based simulations rely on highly simplified models of rule-based human behavior that neglect the complexity of human cognition.
2. Like mathematical models, simulations cannot tell us anything that we do not already know, given the assumptions built into the model and the inability of a computer to do anything other than execute the instructions given to it by the program.
3. Unlike mathematical models, simulations are numerical and therefore cannot establish lawful regularities or generalizations.

The defense against these criticisms centers on the principles of complexity and emergence. How can simple agent-based models explain the rich complexity of social life? In complex systems, very simple rules of interaction can produce highly complex global patterns. "Human beings," Simon contends (1998: p. 53), "viewed as behaving systems, are quite simple." We follow rules, in the form of norms, conventions, protocols, moral and social habits, and heuristics. Although the rules may be quite simple, they can produce global patterns that may not be at all obvious and are very difficult to understand. Hence, "the apparent complexity of our behavior is largely a reflection of the complexity of the environment," including the complexity of interactions among strategically interdependent, adaptive agents. The simulation of artificial worlds allows us to explore the complexity of the social environment by removing the cognitive complexity (and idiosyncrasy) of constituent individuals.

The Exploration of Artificial Worlds

If Simon, Axelrod, and the complexity theorists are right, then the artificiality of agent-based models is a virtue, not a vice. When simulation is used to make predictions or for training personnel (e.g., flight simulators), the assumptions need to be highly realistic, which usually means they will also be highly complicated (Axelrod, 1997: p. 5). "But if the goal is to deepen our understanding of some fundamental process," Axelrod continues, "then simplicity of the assumptions is important and realistic representation of all the details of a particular setting is not." As such, the purpose of these models is to generate hypotheses, not to test them (Prietula et al., 1998: p. xv).

Holland (1995: p. 146) offers a classic example of the problem of building theories that too closely resemble actuality: Aristotle's mistaken conclusion that all bodies come to rest, based on an observation of a world that happens to be infested with friction. Had these observations been made in a frictionless world, Aristotle would have come to the same conclusion reached by Newton and formulated as the principle that bodies in motion persist in that motion unless perturbed. Newton avoided Aristotle's error by studying what happens in an artificial world in which friction had been assumed away. Ironically, "Aristotle's model, though closer to everyday observations, clouded studies of the natural world for almost two millennia" (Holland, 1995: p. 146). More generally, it is often necessary to step back from our world in order to see it more clearly.

For example, Schelling's neighborhood segregation model made no effort to imitate actuality or to resemble an observed city. Rather, the 'residents' live in a highly abstract cellular world without real streets, rivers, train tracks, zoning laws, redlining, housing markets, and so on. This artificial world shows that all neighborhoods in which residents are able to move have an underlying tendency toward segregation even when residents are moderately tolerant. This hypothesis can then be tested in observed neighborhoods, but even if observations do not confirm the predicted segregation, this does not detract from the value of the simulation in suggesting empirical conditions that were not present in the model that might account for the discrepancy with the observed outcome.

In short, agent-based models "have a role similar to mathematical theory, shearing away detail and illuminating crucial features in a rigorous context" (Holland, 1995: p. 100). Nevertheless, Holland reminds us that we must be careful. Unlike laboratory experiments, computational 'thought experiments' are not constrained by physical actuality and thus 'can be as fanciful as desired or accidentally permitted.'

Unwrapping and Emergence

A second criticism of agent-based modeling addresses a problem known as 'unwrapping.' Unwrapping occurs "when the 'solution' is explicitly built into the program [such that] the simulation reveals little that is new or unexpected" (Holland, 1995: p. 137). Critics charge that all computer simulations share this limitation, due to the inability of computers to act in any way other than how they were programmed to behave.

This criticism overlooks the distinction between the microlevel programming of the agents and the macrolevel patterns of interaction that emerge. These patterns are 'built in' from the outset yet the exercise is valuable because the logical implications of behavioral assumptions are not always readily apparent. Indeed, a properly designed computational experiment can yield highly counterintuitive and surprising results. This theoretical possibility is based on the principle of *emergence* in complex systems. Biological examples of emergence include life that emerges from nonliving organic compounds and intelligence and consciousness that emerge from dense networks of very simple switchlike neurons. Schelling's (1971) neighborhood model provides a compelling example from social life: segregation is an emergent property of social interaction that is not reducible to individual intolerance.

Rationality and Adaptive Behavior

A third criticism is that simulation models, unlike mathematical models, are numerical, not deductive, and therefore cannot be used to form generalizations. Worse still, simulations of evolutionary processes can be highly sensitive to the basin of attraction in which the parameters are arbitrarily initialized (Binmore, 1998). This problem is especially acute if the model is deterministic. For example, Axelrod's (1997) model of cultural assimilation appears to demonstrate global diversity, but later work showed that the outcome was a local equilibrium that could be disturbed by very small amount of random cultural mutation (Klemm et al., 2003).

However, game-theoretic mathematical models pay a high price for the ability to generate deductive conclusions: multiple equilibria that preclude a uniquely rational solution. Equilibrium selection requires constraints on the perfect rationality of the agents. Simon appreciates the paradox: "Game theory's most valuable contribution has been to show that rationality is effectively undefinable when competitive actors have unlimited computational capabilities for outguessing each other, but that problem does not arise as acutely in a world, like the real world, of *bounded rationality*" (1998: p. 38). But bounded rationality often makes analytical solutions mathematically intractable. "When the agents use adaptive rather than optimizing strategies, deducing the consequences is often impossible: simulation becomes necessary" (Axelrod, 1997: p. 4). In sum, simulation requires sensitivity analysis and tests of robustness, but properly implemented, it not only offers a solution to the problem of equilibrium selection but can also tell us something about how evolutionary systems move from one equilibrium to another.

Conclusion

From a narrowly positivist perspective, agent-based artificial worlds might seem unrealistic, unfalsifiable, and unreliable, especially when contrasted with earlier approaches to simulation that were data driven, predictive, and highly realistic (e.g., flight simulators). However, agent-based models may be essential for the study of open and complex adaptive systems, whether social, psychological, or biological. When used as an exploratory tool, 'bottom-up' simulation does not test theory against observation. Rather, these thought experiments suggest possible mechanisms that may generate puzzling empirical patterns.

A key theme that runs through these puzzles is that it is often very difficult to recognize the underlying causal mechanisms using conventional data-analytic methods. As Holland concludes (1995: p. 195), "I do not think we will understand morphogenesis, or the emergence of organizations like Adam Smith's pin factory, or the richness of interactions in a tropical forest, without the help of such models."

Social Stratification

David B Grusky, Stanford University, Stanford, CA, USA

Abstract

In all known societies, the most important valued goods (e.g., income, power) are distributed unequally, with the privileged individuals and families enjoying a disproportionate share of them. The term 'stratification system' refers to the institutions that generate observed inequalities of this sort. The main components of such systems are (1) the institutional processes that define certain goods as valuable and desirable, (2) the rules of allocation that distribute these goods across the division of labor, and (3) the mobility mechanisms that link individuals to positions and thereby generate unequal control over valued resources.

The dispassionate observer of the last half-century of social stratification research might easily characterize the field as one of the great success stories of modern social science. The breakthroughs include, for example, (1) building a sophisticated infrastructure for monitoring key trends in poverty, segregation, income inequality, racial and gender inequality, and other labor market outcomes; (2) making real progress in addressing long-standing debates about how much labor market discrimination there is, whether residential segregation matters, how much social mobility there is, and whether social classes are disappearing; and (3) even making headway in understanding the deeper causes of poverty, mobility, and many types of inequality.

Although the progress is considerable, the field's shortcomings are also readily apparent. The most prominent failures have come about when scholars have turned to the idiographic task of understanding the dynamics of change. The spectacular takeoff in income inequality, one of the most consequential developments of our time, went largely unpredicted. The intransigence and resilience of school segregation was clearly not anticipated by many social scientists. The sudden 'stalling out' of long-standing declines in gender inequality remains poorly understood. The equally sudden evaporation of opposition to gay marriage and other type of gay rights would have seemed unimaginable just 5 years ago. The lightning-fast rise and fall of one of the first anti-inequality movements of contemporary US history (i.e., the Occupy movement) is likewise a puzzle.

The objective behind this article is to provide an introduction to the types of questions, both nomothetic and idiographic, that have been and continue to be taken on in the field of poverty and inequality. It would be impossible to provide some encyclopedic introduction to all that is known in this sprawling field. It is tractable, however, to present the *types* of questions that have been taken on, with a special emphasis on understanding how those questions have changed and evolved. Before turning to this task, it will be helpful to introduce some of the basic concepts used to describe the structure of inequality, the persistence of inequality, and the effects of inequality on social behavior.

Basic Concepts

The key components of stratification systems are (1) the institutional processes that define certain types of goods as valuable and desirable, (2) the rules of allocation that distribute these goods across various jobs or occupations in the division of labor (e.g., doctor, farmer, homemaker), and (3) the mobility mechanisms that link individuals to jobs and thereby generate unequal control over valued resources. It follows that inequality is produced by two types of matching processes: The social roles in society are first matched to 'reward packages' of unequal value, and individual members of society are then allocated to the positions so defined and rewarded. In all societies, there is a constant flux of occupational incumbents as newcomers enter the labor force and replace dying, retiring, or out-migrating workers, yet the positions themselves and the reward packages attached to them typically change only gradually. As Schumpeter (1953) puts it, the occupational structure can be seen as "a hotel … which is always occupied, but always by different persons."

What types of rewards are distributed via these two matching processes? It is increasingly fashionable to recognize that inequality is 'multidimensional,' that income is accordingly only one of many important resources, and that income redistribution in and of itself would not eliminate inequality (e.g., Sen, 1997). When a multidimensionalist approach is accordingly taken, one might usefully distinguish among the eight types of assets listed in **Table 1**, each understood as valuable in its own right rather than a mere investment item. The assets of **Table 1** may of course serve investment as well as consumption functions. For example, most economists regard schooling as an investment that generates future streams of income, while some sociologists likewise regard social networks as forms of capital that can be parlayed into educational credentials, income, and other valued goods. While most of the assets listed in **Table 1** are clearly convertible in this fashion, they are not necessarily regarded as investments by the individuals involved. In fact, many valuable assets can be secured at birth or through childhood socialization (e.g., the 'good manners' of the aristocracy), and they are therefore acquired without the beneficiaries explicitly weighing the costs of acquisition against the benefits of future returns.

The implicit claim underlying **Table 1** is that the listed assets exhaust all possible consumption goods and, as such, constitute the raw materials of stratification systems. The stratification field has developed a vocabulary that describes how these raw materials are distributed across members of the

Table 1 Types of assets and examples of advantaged and disadvantaged groups

Assets		*Examples*	
Asset group	*Examples of types*	*Advantaged*	*Disadvantaged*
1. Economic	Wealth	Billionaire	Bankrupt worker
	Income	Professional	Laborer
	Ownership	Capitalist	Worker (i.e., employed)
2. Power	Political power	Prime minister	Disenfranchised person
	Workplace authority	Manager	Subordinate worker
	Household authority	Head of household	Child
3. Cultural	Knowledge	Intelligentsia	Uneducated persons
	Digital culture	Silicon Valley residents	Residents of other places
	'Good' manners	Aristocracy	Commoners
4. Social	Social clubs	Country club member	Nonmember
	Workplace associations	Union member	Nonmember
	Informal networks	Washington A-list	Social unknown
5. Honorific	Occupational	Judge	Garbage collector
	Religious	Saint	Excommunicate
	Merit-based	Nobel Prize winner	Nonwinner
6. Civil	Right to work	Citizen	Unauthorized immigrant
	Due process	Citizen	Suspected terrorist
	Franchise	Citizen	Felon
7. Human	On-the-job training	Experienced worker	Inexperienced worker
	General schooling	College graduate	High school dropout
	Vocational training	Law school graduate	Unskilled worker
8. Physical	Mortality	Person with long life	A 'premature' death
	Physical disease	Healthy person	Person with AIDS, asthma
	Mental health	Healthy person	Depressed, alienated

population. The main parameters of interest pertain to (1) the overall amount of inequality, (2) the extent to which individuals are locked permanently into certain positions (i.e., rigidity), (3) the extent to which ascriptive traits fixed at birth are used for purposes of allocation, and (4) the degree to which the various dimensions of inequality cohere (or are 'crystallized'). These four types of parameters are reviewed below.

The overall *amount of inequality* in any given resource (e.g., income) may be defined as its dispersion or concentration among the individuals in the population. Although many scholars seek to characterize the overall level of societal inequality with a single parameter, such attempts will obviously be compromised insofar as some types of rewards are distributed more equally than others. This complexity clearly arises in the case of contemporary inequality regimes. The recent diffusion of 'citizenship rights,' for example, implies that civil goods have come to be widely dispersed across all citizens, whereas economic and political goods continue to be disproportionately controlled by a relatively small elite.

The *rigidity* of a stratification system is indexed by the continuity (over time) in the social standing of its members. The stratification system is highly rigid, for example, if the current wealth, power, or prestige of individuals can be accurately predicted on the basis of their prior statuses or those of their parents. It should again be emphasized that such rigidity (or 'social closure') will typically vary in degree across the different types of assets listed in Table 1.

The stratification system rests on *ascriptive processes* to the extent that conditions present at birth (e.g., parental wealth, sex, race) influence the subsequent social standing of individuals. If ascriptive processes of this sort are in operation, it is possible (but by no means guaranteed) that the underlying traits themselves will become bases for group formation and collective action (e.g., race riots, feminist movements). In contemporary societies, ascription of all kinds is usually seen as undesirable or discriminatory, and much governmental policy (e.g., antidiscrimination legislation) is therefore directed toward fashioning a stratification system in which individuals acquire resources solely by virtue of their achievements.

The degree of *crystallization* is indexed by the correlations among the various resources (e.g., income, wealth, education) that are socially valued. If these correlations are strong, then the same individuals (i.e., the 'upper class') will consistently appear at the top of all hierarchies, while other individuals (i.e., the 'lower class') will consistently appear at the bottom of the stratification system. By contrast, various types of status inconsistencies (e.g., a poorly educated millionaire) will emerge in stratification systems with weakly correlated hierarchies, and it is correspondingly difficult in such systems to define a unitary set of classes that have predictive power with respect to all resources.

Although the preceding terms are fundamental to the field, there are of course a great many others, some of which will be introduced below. The following sections lay out the nine subfields around which the field of inequality has been organized.

The Functions and Dysfunctions of Inequality

In economics and sociology alike, there is a long tradition of theorizing that emphasizes that some forms of inequality

have the positive effect of (1) inducing the most qualified workers to take on the important jobs and (2) incentivizing people to work hard and innovate. The famous trade-off thesis implies that a taste for equality is exercised at the cost of reducing output and potentially rendering all worse off. We cannot, as Okun (1975) so cleverly put it, "have our cake of market efficiency and share it equally." Although some scholars have taken the trade-off thesis as an article of faith (e.g., Davis and Moore, 1945), others treat it as testable by asking whether groups or societies with higher inequality are indeed more productive.

The trade-off thesis of course implies that inequality is functional only insofar as it delivers the proper incentives. There are many ways in which high-inequality regimes may not be incentivizing all people to work hard in ways that then increase total output. If, for example, inequality takes a simple winner-take-all form, it could be counterproductive and serve to reduce output. The relevant thought experiment here is that of the golf tournament in which all prize money is allocated exclusively to the winner (e.g., Freeman, 2012). In this setup, mediocre golfers who never had a chance of winning lack any incentive to exert themselves, with the implication that total output (as measured, say, by total strokes) will diminish. There are, in other words, certain forms of extreme inequality that may not succeed in creating the incentives that the trade-off thesis presumes. Likewise, insofar as inequality arises because of corruption and rent-seeking behavior, it is not contributing to overall output and cannot be justified in functionalist terms. There is presumably no collective benefit, for example, to allowing a chief executive officer to pack the board with cronies simply because they will then vote him or her a generous compensation package (see DiPrete et al., 2014). The current debate about the importance of rent and corruption in generating the takeoff in income inequality (e.g., Grusky, 2012) is motivated by precisely this interest in assessing whether extreme inequality of the sort observed today can be understood as efficient or functional.

Inequality in Comparative Perspective

If inequality is a ubiquitous feature of human society, it nonetheless has taken on many different forms. There is a long tradition of stratification research examining the historical and cross-national variability in the amount of inequality, the types of assets that underlie inequality (e.g., power, prestige, economic resources), the extent to which opportunities vary with social origins and other ascriptive traits, and the ideologies by which prevailing inequalities are legitimated. Although the differences across tribal, feudal, caste, socialist, and capitalist forms of inequality are especially stark on these and other dimensions (see Grusky and Weisshaar, 2014), even within contemporary capitalist societies the institutional variability is arguably impressive (see Esping-Andersen and Myles, 2008). In popular commentary, it is sometimes assumed that market economies are associated with a single characteristic form of inequality, but in fact the evidence clearly reveals the wide variety of ways that inequality has been and continues to be organized within market economies.

The same lesson is readily gleaned by examining how income inequality has evolved over the last century within market societies. As Atkinson et al. (2011) show, the trend in income inequality follows a U-shaped form in the English-speaking countries (i.e., the US, Canada, Ireland, the UK, Australia, and New Zealand), all of which run so-called liberal market economies. In each of these countries, we see inequality dropping precipitously in the late 1920s and during World War II, stabilizing at a comparatively low level over the next 30 years, and then taking off in the 1970s and ultimately returning to or approaching the extreme levels that prevailed in the 1920s. By contrast, a rather different pattern emerges for the Central European countries, such as France and Germany, that are running so-called coordinated market economies. Although these countries also underwent a real decline in inequality during the first half of the twentieth century, that decline is not followed by any subsequent rebound in inequality of the sort found in the US and the other English-speaking countries. Instead, one finds a rough stability in the amount of inequality or, in a few cases, even a continuing slight decline. Over the last quarter century, there has been much research on why some countries are experiencing a spectacular takeoff in income inequality, whereas other countries are experiencing a slow takeoff, a delayed takeoff, or none at all.

The Structure of Inequality

Because so much social science research is now focused on the takeoff in inequality, we have a growing body of knowledge on what is driving it (e.g., Goldin and Katz, 2008) and who benefited most from it (e.g., Hacker and Pierson, 2010). We know less, however, about the form that inequality takes. This is surprising because some of the most contentious debates within sociology are about the form rather than extent of inequality. Although most sociologists assume that inequality is organized around big social classes (e.g., capitalists, managers, craft workers) that affect the politics, interests, and life chances of their members, there is much debate about (1) exactly how big such classes are, (2) how best to draw the boundaries between them, and (3) what types of assets underlie them.

Because class models are discussed in detail in the article on social class, it is unnecessary to review them in much detail here. It is worth pointing out, however, that these debates about the form of inequality, although pursued rather obsessively in some quarters, do nonetheless speak to issues of some consequence. If the objective, for example, is to understand the experience of poverty, one should care whether those with low income tend also to have very little in the way of other resources, such as wealth or education. We should presumably be more troubled by a form of poverty in which many types of disadvantage (e.g., income, wealth, education) tend to come together. The form that inequality takes will also likely affect how it is experienced and whether it is well tolerated. In a highly crystallized system, an economic crisis might generate a resurgence of class-based rhetoric, with the sharpest vitriol aimed at a culturally homogenous upper class with distinctive lifestyles, attitudes, and behaviors. In a less crystallized system, the same economic crisis might generate a more fragmented

political discourse, perhaps equally contentious in its own way but with little coherence across issues and a weaker 'us versus them' rhetoric.

The main alternatives to class models are those that represent the stratification system in gradational terms. The gradational formulation, which was especially popular in the 1970s and 1980s, represents inequality either as a hierarchy of *individuals* differing in their income, wealth, or education or a hierarchy of *occupations* differing in their prestige or socioeconomic status. Although gradational models based on occupational prestige or socioeconomic status have largely disappeared from the day-to-day practice of inequality research, gradational models based on individual-level income, wealth, and education remain very popular. The demise of scales based on occupational prestige or socioeconomic status seems as much due to the inevitable half-life of any research tradition as to any hard empirical evidence that this form of gradationalism is any less important now than in the past.

The Ruling Class, Elites, and the Upper Class

There is a long tradition of stratification research exploring how power, privilege, and money may come together to form an elite at the top of the social hierarchy. In recent years, the 'one percent' has become the modern-day label for the elite, but few commentators would probably seriously believe that an arbitrary income threshold of that sort captures very well the structure of power and advantage at the top.

The key question within this research tradition is whether late industrial societies tend to generate a powerful and solidary upper class. The 'power elite' narrative (see Mills, 1956) has it that economic, political, and military elites form a unitary class by virtue of coresiding in the same neighborhoods, belonging to the same clubs, sharing a coherent political ideology, and interacting as approximate equals. This small elite occupies positions of considerable power and can therefore "mightily affect the everyday worlds of ordinary men and women" (Mills, 1956). As against this account, we might imagine that capitalists, by virtue of their economic power, have become the *de facto* 'ruling intellectual force' (Marx, 1970). Although top leadership positions are of course formally filled by political or military elites, it is hardly radical any more to suggest that they are acting largely at the behest of capitalists and corporations (who wield influence via lobbying, campaign funding, and the like).

More recently, Gouldner (1982) has suggested that a third claimant to power, the 'knowledge class,' is in ascendancy as expert knowledge comes to be understood as a source of value and a prerequisite for responsible and successful leadership (also Brooks, 2000). For new class theorists, the main struggle of the contemporary period is not between capitalists and workers (as workers long ago lost out), rather it is found in the ongoing 'civil war' (Gouldner, 1982) between capitalists with the power to buy influence and intellectuals who claim to have the knowledge to successfully wield it. The outcome of this civil war is far from obvious: If capitalists bring ever-growing economic power to the table, intellectuals rest their case on the efficiency of relying on results-driven scientific and expert knowledge.

Poverty and the Underclass

When stratification scholars have turned their attention to the bottom of the class structure, a rather different set of questions has tended to emerge. The scholarship on elites has typically emphasized the power struggles between competing factions (e.g., capitalists, intellectuals, political elites), whereas the scholarship on poverty has instead focused on the various *external forces* that have affected the amount and experience of poverty. These forces take the form of (1) impersonal economic factors (e.g., globalization) that have eliminated manufacturing jobs for low-skill workers (e.g., Wilson, 2011); (2) the relatively anemic redistributive programs within the US as a whole (e.g., Kenworthy, 2011) and the southern US more specifically (e.g., Newman and O'Brien, 2011); (3) the extremely high rates of incarceration among blacks (e.g., Western and Pettit, 2010); (4) the role of concentrated poverty in reducing access to jobs, good schools, and other neighborhood assets (e.g., Massey and Denton, 1993); and (5) the lasting effects of early childhood stress on cognitive development (e.g., Evans et al., 2011). The foregoing literature on the institutional sources of poverty is joined, of course, by much research on individual-level 'risk factors' that predispose one to poverty. It is well known, for example, that poverty rates are especially high among children, young adults, the less educated, blacks and Hispanics, and female heads of households (Danziger et al., 2012).

The institutional factors listed above combine to produce an unusually high poverty rate in the US. In 1973, the official poverty measure dropped to a historic low of 11.1%, but that level was never again achieved over the course of the following four decades. The recent recession, like most prior ones, has caused a surge in poverty. The official measure of poverty is currently near its highest level in the last half-century, and most scholars expect that poverty will remain high for many more years (Danziger et al., 2012).

Social Mobility

The language of stratification theory makes a sharp distinction between the distribution of social rewards (e.g., the income distribution) and the distribution of opportunities for securing these rewards. As sociologists have frequently noted, it is the latter distribution that governs popular judgments about the legitimacy of stratification: The typical American, for example, is quite willing to tolerate substantial inequalities in power, wealth, or prestige provided that the opportunities for securing these social goods are distributed equally. If the competition has been fairly run, most Americans are untroubled by a stratification system that amply rewards the winners. This line of reasoning has motivated a long tradition of research on social mobility examining whether the US is living up to this commitment to a fairly run race in which everyone, no matter how humble his or her origins, has ample opportunities to get ahead.

It is conventional to carry out such research with 'mobility tables' that represent the intergenerational flows between origin and destination class categories (e.g., Jonsson et al., 2011). These tables tell us, for example, how frequently

children born into the craft category move up to the professional or managerial sector, remain within the craft category, or move down to less skilled manual work. It is of course not possible on the basis of such raw observational data to make any straightforward assessment of the opportunities that have been made available to children born into each social class. This is partly because standard outcome-based measures of inequality are tainted by the confounding effect of differential tastes. For example, a worker with a well-developed taste for leisure may opt to work for relatively few hours, leading to low earnings but nonetheless optimal utility (by virtue of the high valuation placed on leisure).

Whenever differential outcomes are generated through the operation of differential tastes, some scholars would argue that the resulting differences in outcomes are unproblematic, as they simply express trade-offs that are being made between different types of valued goods (e.g., leisure and income). This argument implies that we should measure the distribution of opportunities that prevails before differential tastes can express themselves. The key objective under this formulation is to determine whether 'capabilities' (i.e., opportunities to secure rewards) are equally distributed, not whether rewards themselves, which reflect the operation of tastes, are equally distributed. It bears noting that, insofar as tastes themselves are endogenous (because, for example, children may cathect with their parents), it becomes yet more difficult to tease out the way in which social origins constrain destinations on the basis of conventional observational data.

This is all to suggest that one cannot read the mobility table as expressing straightforwardly the extent to which opportunities are unequally distributed. Even so, most sociologists and social scientists tend to hold aside all such complexities, and analyses of mobility tables are thus understood as exposing, if only imperfectly, the extent to which the liberal ideal of an open system has been realized. This objective underlies analyses of (1) the gross association between occupational origins and destinations, (2) the extent to which children garner a return from advantaged economic origins, (3) the extent to which educational investments are a key mediating variable between origins and destinations, (4) the role of social psychological variables, such as aspirations and expectations, in affecting the process of attainment, (5) the effects of networks on occupational and other outcomes, and (6) the effects of labor market institutions (e.g., unions) on remuneration and bargaining power.

Racial and Ethnic Stratification

When scholars study social mobility, they are of course exploring a particular form of ascription, a form that arises insofar as children born into well-off families are advantaged in the labor market, the marriage market, and in the competition for other valued resources. But of course class-based ascription is but one of many forms of ascription. Especially in the US, racial and ethnic inequalities are also very potent examples of ascription, and a large body of scholarship has accordingly developed to understand its causes and effects.

The obvious starting point in studying racial and ethnic inequality is to understand how the classification schemes themselves (e.g., 'black,' 'white,' 'Asian') come to be constructed and reconstructed over time. It is important, for example, to understand the processes by which such schemes come into being and are reproduced (see Omi and Winant, 1986) as well as the processes by which individuals are sorted (and sort themselves) into such schemes as are already in place (Saperstein and Penner, 2014). There is an increasingly large literature showing that racial and ethnic identities, far from being ascriptively fixed at birth, are in fact very malleable over the course of one's life.

As important as these processes are, there is yet more research on the dynamics by which entire immigrant groups, not just particular individuals, are sorted into the racial and ethnic system within the host country. This line of research examines, for example, whether new entrants are assimilating in 'straight-line' fashion (e.g., Alba and Nee, 2014), whether especially large and ongoing immigrant streams work to interrupt such straight-line assimilation (e.g., Jiménez, 2014), and whether ethnic enclaves work to hinder or impede the incorporation process (e.g., Portes and Manning, 1986).

There is also much research on the forces making for change and stability in racial and ethnic inequality. Because our various institutions have all been profoundly racialized, there are accordingly many institutional arenas in which change might occur, a point that Wilson (2011) nicely makes. At various points in US history, we have witnessed profound transformations of racial and ethnic inequality, transformations that appear to be linked to changes in residential segregation (e.g., Massey and Denton, 1993); changes in interracial assortative mating (Qian and Lichter, 2014); changes in laws, norms, and institutional forms (e.g., Sampson, 2012); and of course economic changes and transformations (e.g., Wilson, 2011).

Gender Inequality

It was once fashionable to argue that all forms of ascription are fated to wither away because they (1) rest on a caste-like allocation of labor that ignores considerations of merit and talent, and (2) are inconsistent with our moral commitment to running an equal-opportunity society (Parsons, 1970). By this logic, the ascription that persists to this day is but a residual holdover, with the twin forces of efficiency and egalitarianism slowly but gradually wearing it away.

It is of course by now clear that racial, ethnic, and class-based forms of ascription are deeply resistant to change even under the pressure of these forces. Although the same may be said of gender-based ascription, the gender form is nonetheless distinctive by virtue of playing out so prominently *within* families. Because we watch 'up close and personal' the gender division of labor in our families, we are under special pressure to believe essentialist stories justifying it, stories that represent women as especially suited for nurturing or service and men especially suited for cognitive or manual labor. These stories, so some have argued (see Charles and Grusky, 2011), take on a powerful life of their own, tend to legitimate and perpetuate an essentialist division of labor, and thereby impart a special staying power to gender-based ascription.

For this and many other reasons, we might expect gender inequality to evolve under a logic that may differ from that

governing racial, ethnic, or class inequalities. There is a long stream of research on gender exploring whether indeed gender is subject to a very distinctive logic of change. This research takes on such questions as whether women are 'opting out' of the workplace (e.g., Percheski, 2014), whether there is still much discrimination against women and mothers (e.g., Correll et al., 2008), whether there are 'glass ceilings' and other forms of workplace hypersegregation (e.g., Gorman and Kmec, 2014), and whether there is a recent 'stalling out' in the historic declines in gender inequality (e.g., England, 2010).

The Consequences of Inequality

The subfields discussed to this point have addressed the form and causes of inequality. By contrast, the classical literature on inequality, most notably that of Marx (1970), focused on the macrolevel *effects* of inequality, especially its implications for systemic change (e.g., revolution). This macrolevel tradition lives on today in the form of cross-national studies of inequality on total economic output, ethnic unrest, democracy, and much more. It also continues in the form of speculative commentary on the various ways in which present-day inequality regimes contain within them the kernel of future inequality regimes.

Although the macrolevel tradition is still in play, there is more research today on the comparatively modest question of how an individual's position within an inequality regime affects the course of her or his life. The scholars working within this microlevel tradition examine the effects of an individual's class position on (1) lifestyles, tastes, and consumption practices (e.g., Bourdieu, 1984); (2) childrearing and socialization practices (e.g., Lareau, 2003); (3) political attitudes and voting behavior (e.g., Frank, 2004); and (4) opportunities for a long and healthy life (e.g., Lutfey and Freese, 2014). It should come as no surprise that the effects of inequality are so wide-ranging. In contemporary societies, most everything is marketized and commodified, meaning that one's participation across a wide variety of domains is directly affected by the capacity to pay for that participation. There is still much debate over the appropriate reach of commodification, but that debate occurs within a more circumscribed range than it once did.

Conclusion

Is there any theme running through the many questions that sociologists of inequality have taken on? The field is of course sprawling and the questions of course diverse. If pressed nonetheless to identify a theme, all that can be noted is the characteristically modern tendency to problematize inequality, to ask how it came about, and to inquire as to the mechanisms generating it.

This problematizing orientation is distinctively modern in its underpinnings. For the greater part of human history, the stratification order was regarded as an immutable feature of society, and the objective of commentators was to explain or justify this order in terms of religious or quasi-religious doctrines (e.g., Bottomore, 1965; Tawney, 1931). It was only with the Enlightenment that a critical rhetoric of equality emerged in opposition to the civil and legal advantages of the aristocracy and other privileged status groupings. In its most radical form, this egalitarianism led to Marxist interpretations of human history, and it ultimately provided the intellectual underpinnings for socialist stratification systems. While much of stratification theory has been formulated in reaction and opposition to these early forms of Marxist scholarship, the field nonetheless shares with Marxism the distinctively Enlightenment premise that individuals are to be equally valued and respected regardless of differences in their economic or social standing (see Meyer, 2001). In part, the questions laid out here reflect this tension between the brute facts of extreme and sometimes growing inequality and the modern commitment to at least *some* forms of equality, at minimum an equality of respect and of opportunity.

Abstract

Social structure is about patterns of relations. Two main families of approaches conceive these patterns differently. One, a top down one, tends to see a global organization as stemming from a common shared culture. The second, a bottom up, pays more attention to agglomerative processes that begin with individuals who may or may not begin with shared cultural templates.

Social structure refers to patternings in social relations that have some sort of obduracy. Within this general definition, there are two primary families of more specific approaches. In the first, 'structure' may be used to refer on the macro level to the abstract organization of reciprocally defined social categories that are seen to comprise some social whole. In the second, the term can be used to refer to smaller scale 'social structures,' configurations of concrete relationships among individuals without reference to a notion of a larger societal totality. We organize our exposition accordingly. (We note that Porpora (1989) in addition gave as conceptions of social structure first, that of Anthony Giddens, which we treat here as an extreme form of the first understanding of structure, and second, relations between variables, but we have not seen any examples of people claiming this as a definition of structure, and we discuss this under the related heading of *social systems* below.)

Structure as Abstract Relations between Social Positions

Although all the approaches in this category link structure to some sort of organization of positions or types that anchor action, they differ as to the logic of the organization of the positions that may variously be taken to be social functions, roles, or classes.

Structure and Function

The idea of 'social structure' was first introduced by Herbert Spencer (e.g., 1896[1873]: pp. 56–60). At the time, the word 'structure' in biology referred to what we would now call 'organs,' sets of contiguous tissue that performed a specifiable function for the organism as a whole. Spencer argued that society had 'social structures' that carried out social functions.

Thus the root of the idea of social structure comes from the organismic metaphor applied to society. This metaphor is certainly an old one; in the Western tradition we often begin with Plato, who (we now say) suggested that the city might be understood as a 'man writ large,' and thus a convenient place for an anthropology. (In the *Republic* (II:368d) Plato argues that, given that those of us with imperfect vision have an easier time reading larger letters, we should find a place to study the nature of justice similarly writ large, and that is the city. From here, he uses our interdependence to derive the need for specific occupations, for specialization, and for trade (369–371).) Now indeed, Plato did suggest a mapping between characteristics of persons and those of the city. Most important, Plato made a distinction between (what might appear to us as) cognition, emotions, and instincts. Thus in the fourth book of the *Republic* (espec. §436), Plato had Socrates demonstrate that there are three parts of the soul that have different functions – that we "learn with one part of ourselves, feel anger with another, and with yet a third desire the pleasures of nutrition and generation." (The physical organs to which these were taken to correspond were for many centuries taken to be the head, the heart, and the liver, organized in a vertical hierarchy.) So too, he argued, the city has three classes, each of whom must do its part. Some make things (or 'make money,' corresponding to the appetitive), some make rules (corresponding to the *nous*, the intellect), and some make war. These correspond to three qualities of the good city, which should be wise (the wisdom of the city is the wisdom of its counselors), brave (the bravery of the city is the bravery of its fighters), and sober (*Republic*, §428–434). Now despite his famous emphasis on our interdependence and even on the division of labor, Plato did not propose an organismic model of the state, and it seems that no such developed analogies arose in Europe until the mass of differentiable urban occupations were no longer associated with servile status.

With the rise of materialist views of human beings and of society, organismic metaphors were extended into more developed allegories: thus Hobbes (1943[1651]: pp. 8, 171, 183–188, 193f., 246–257) proposed correspondences in the body politic to nerves, blood and joints, and could liken its states of illness to pleurisy, Siamese triplets, and constipation. But despite his categorical rejection of metaphor, Hobbes's use of the organismic language stemmed as much from his love of pursuing a simile as from his explanatory goals. (Thus not only is the distribution of goods analogous to nutrition, but these good ultimately come from either the land or the sea, '(the two breasts of our common Mother),' adds Hobbes (1943[1651]: p. 189).) Certainly, Hobbes treated the organismic predicate as one of metaphor and not as one of identity (e.g., systems "*may be* compared … to the similar parts of man's body" (emphasis added)), and alternated between it and others (the commonwealth as building, as Leviathan, or as 'Mortall God').

Although such organismic metaphors remained popular, we do not know of any attempt to produce a serious and detailed exposition until Spencer. Comte (1974[1842]: 510ff) too had advanced an organismic metaphor by applying it to the societal division of labor, examining the laws according to which the societal whole develops and how the whole regulates its constituent organs. But Comte's overriding theme of wholism (and his impatience to begin wholesale social reconstruction) led him to neglect a detailed consideration of the parts.

By contrast, Spencer argued that the functional needs of the whole not only were met by the parts (like Plato), nor that there were laws of development of the whole (like Comte), but that structures (and functions) have their own developmental tendencies that direct the social organism's course of development. ("Just as in the man there are structures and functions which make possible the doings his biographer tells of, so in the nation there are structures and functions which make possible the doings its historian tells of; and in both cases it is with these structures and functions, in their origin, development, and decline, that science is concerned" (Spencer, 1896[1873]: p. 52).) Further, despite his use of the organismic metaphor, Spencer (e.g., 1910: p. 244) always saw the functions that were met by social structures as being, at base, functional needs of the *individuals* who composed society (and not those of the social whole apart from the individuals). Human action is fundamentally driven to meet human needs and wants such as defending against enemies and obtaining food. Individuals cooperate to fulfill those ends, giving rise to structures. Thus 'social structure' referred to the internal organization of the social whole arising as a by-product of the functional interdependence of human life (a point that Malinowski was later to reiterate).

The organismic analogy developed in ways charted by Kaufmann (1908) and Levine (1995). What was crucial for sociology and anthropology was the duality of structure and function that was accepted by Durkheim (most notably in *The Division of Labor*) and elaborated by Radcliffe-Brown.

Like Spencer and Comte, Durkheim proposed that society is structured according to the functions that social groups fulfill in the division of labor. But while Spencer retained an emphasis on the ontological primacy of the individual, Durkheim unreservedly based his theory in the *sui generis* existence of social order. He examined how the functional interdependence upon which the division of labor is based served as society's source of social solidarity. The most fundamental 'function' in society is the division of labor's function of integrating and uniting the societal organism, thereby sustaining its life (1933[1893]: p. 11). While mechanical solidarity – solidarity based on individuals' similarities – was the dominant foundation for social bonds in earlier epochs, modern society, according to Durkheim, is bound primarily by 'organic' solidarity – solidarity that arises from individuals' interdependence in the societal division of labor. Differentiated social groups comprise a system of 'organs' (p. 132), each of which performs a specialized duty that sustains the whole. These organs are bound to each other by relationships of functional interdependence (pp. 83, 173), where the survival of the whole depends on each organ performing its specific duty. The more specialized the function of an organism, the more integrated and developed the society.

This perspective was influential in anthropology, largely mediated by the work of Radcliffe-Brown (1952: p. 179), who emphasized that a structure 'is thus to be defined as a set of relations between entities.' Further, while other theorists had focused on a few roles as key – kinship or occupation, most notably – Radcliffe-Brown (1952: 191f) argued that such structure had to be understood as involving *all* such relations. This suggested a more complete vision of an all-encompassing and mutually consistent social structure. Strangely, sociology tended to be influenced by earlier work in anthropology that drew more upon notions of kinship than social functions, perhaps because it had clearer implications.

Structure as Role

In particular, anthropologist Ralph Linton (1936) had suggested a second duality (after that of structure/function), namely that of status and role. A status, argued Linton (1936: p. 113) is a slot in social structure, or as he said (he used the idea of social 'systems,' not 'structures'), 'a position in a particular pattern.' Such a position has both rights and duties associated with it, and action in accordance with these is the performance of a *role*. Thus the role is the active counterpart to the status, the verb form as opposed to the noun. (One will note that in English, perhaps the bulk of early terms for common objects also have proper usage as verbs: to hammer is to use a hammer, to water is to put water on, and so on. So too a mother mothers, and this is a status 'roling.')

A number of sociologists have similarly examined social structure as an organized set of roles. This 'structure' was increasingly understood by sociologists as one-half, or one-third, of the realm of study at hand. Pitrim Sorokin (e.g., 1962) proposed a triad of *personality*, *society*, and *culture* (though he is more known for employing the latter two as a pair), and this triad was also adopted by both his younger colleague (and nemesis), Talcott Parsons and his graduate student, Robert Merton. Both saw the 'social' dimension as referring to something structural, and both paradigmatically took this to mean the organization of social roles, thus preserving the Lintonian duality. Parsons in particular emphasized the close mapping between structure and culture. In Parsons's (1961) words, "the structure of social systems … consists in institutionalized patterns of normative culture." Societal roles, in other words, are defined by specific norms that prescribe rules for behavior.

Robert Merton (1957) also explicitly began with this understanding of social structure, and indeed said "status and roles become concepts serving to connect culturally defined expectations with the patterned conduct and relationships which make up a social structure." (Parenthetically, we also note that Merton (e.g., 1976) maintained an interest in the emerging structuralist theories and believed them related to his own structural approach. We return to this branch below.)

In sum, this approach to social structure tended to emphasize culture, and see structure as, at least in the long-run equilibrium, a nonproblematic objectivation of cultural patterns. This priority tended to be reversed in most approaches that drew from Marx.

Structure and Class

Now we have said that Spencer was the first to use the term 'social structure,' and this is indeed true. However, Marx had

used similar language, and, with Engels in *The German Ideology* (Marx and Engels, 1976[1845–1846]: 35f), had written "The social structure and the state are continually evolving out of the life-process of definite individuals, however, of these individuals, not as they may appear in their own or other people's imagination, but as they *actually* are; i.e., as they act, produce materially, and hence as they work under definite material limits, presuppositions, and conditions independent of their will." The term translated as social structure, namely *gesellschaftliche Gliederung* (*Werke*, 3:25) carries more connotations of organization or arrangement, and somewhat fewer of a construction. Marx's conception in its most general is to emphasize what he called (in the 'Theses on Feuerbach') the 'ensemble of societal relations' (*Werke* 3:7).

The social relations of paramount interest to Marx were economic ones, more specifically, the social relations of production. These relations appear in juridical form as property relations, but in social form as the relations between classes. It is this set of relations that Marx argued constituted the 'economic structure' of society; the 'superstructure' erected on top of this includes legal, political, and ideological formations that have some degree of homology to the underlying economic structure (*see* Marxism). Thus as in the previous conception of social structure, we have a close duality between cultural understandings and patterns of relations. But while the first conception privileged the cultural realm as having explanatory priority, here it is the pattern of relations that must be understood first.

Structure as Culture as Structure

These conceptions tend to establish a duality between what one's position in structure is, and what one does; we have seen that in the Lintonian and Parsonian versions, this implies a duality between social structure and aspects of culture. This was taken to its logical vanishing point in the work of Anthony Giddens. Giddens decided to claim as 'structure' in social systems 'rules and resources,' arguing (e.g., 1979: pp. 64–66) that structure exists only as the structural – indeed, the structuring – properties of a social system. (Here he seems to have been influenced by the conception of structuralism discussed below.) Although intellectually pleasing, by placing a heap of social structure in the heads of the actors (in the form of rules), Giddens, wittingly or unwittingly, sent social theory careening down a hill in which structure and culture would end up being not simply dual, but indistinguishable. This was associated with further confusions.

For whether it is the expectation that the duties of the younger sister include looking after aging parents, or it is the class relation that the proletariat does not own the means of production but instead sells labor power, social structure was easily assimilated to constraint and restriction of individuals. As a result, especially in Britain, there arose a conviction that social action could be analyzed as a two-part beast, one part the structural constraint and the other, agency. Unlike the seemingly homologous division of the self by Mead into the 'me' (including, 'what they expect me to do') and the 'I' ('what I *actually* did'), here most conceptions made a differentiation between those actions that *reproduced* structure (and hence had no valid claim to agency) and those that challenged, transformed, or at least grumbled about the structure. But with the transition from (1) structure being defined as organized relations to (2) structure being defined by its pernicious effects, we leave the realm of sociology, and hence do not pursue this approach further. Instead, we briefly indicate how these top-down conceptions of social structure influenced and then were influenced by the development of two related concepts.

Continuities

Systems Theory

This conception of social structure influenced the development of two relatively coherent schools of thought, treated separately in this volume. The first is systems theory (*see* Systems Theory), which also started with the organismic metaphor (indeed, when Hobbes spoke of 'social systems,' he was using the then-current term 'system' for 'organ'). Modern systems theory, the rise of which is often assumed to begin with Ludwig von Bertalanffy's (1968) work in the 1940s, explores the regularities that emerge when sets of elements – whether physiological, environmental, or social – assume such a form that they become self-regulating. In other words, they maintain themselves within a range of possibilities (a state space) through self-correcting feedback mechanisms. In the context of social science, systems theory explores how societies remain stable and functioning as their constituent parts cooperate and adapt to one another. What is important for us is the effects that this had on notions of social structure.

Talcott Parsons first popularized a systems approach to the study of social structure in *The Social System* (1951). He went on to propose four systemic necessities – basic functions that systems must perform in order to maintain their existence – as key to understanding the organization and development of societies. Parsons tended to propose subsystems that were defined *wholly functionally* (and not structurally), and to examine the media that various subsystems used to order their relations or to interact with other subsystems. To the extent that such systems thinking was taken seriously, it tended to lessen interest in social structure as such (an emphasis preserved by Merton, who maintained an ambivalent relation to the idea of systems).

A further divergence of systems and structural thinking came with the work of Luhmann. Once mentored by Parsons, Niklas Luhmann developed a rival approach to systems theory whose core is communication rather than action. Humans are not coordinated into action systems but systems of observing and sense making. Actors confront an external environment in which massive amounts of information circulate. As they observe, select out, and make sense of, bits of information, the system is constituted (1996: p. 24). By observing the environment, the observer distinguishes between himself and the environment, and this act of distinction brings the observer into being. What is essential for us are three points: first, the components here are acts of communication, not social relationships. Second, there is a self-organization (*autopoiesis*) of this set of communications that may be largely decoupled from the needs of organic individuals. Third, such systems are more than a mere analytical tool that elucidates societal processes; rather, 'systems exist' (1995: p. 12). Thus although Luhmann did argue that the major social subsystems corresponded to well-understood realms (which he

successively explored: law, art, politics, religion, economy and education), we must be prepared for functional sub-sub-systems that are potentially divorced from needs of individuals and even from the role structure.

Structuralism

The second offshoot is the line of thought termed 'structuralism' (*see* Structuralism). This tradition in many ways branched off of Comte and Durkheim; although it is generally understood to have originated with the structural linguistics of Ferdinand de Saussure, Saussure himself was influenced by Durkheim's Comtean division between statics and dynamics. Saussure argued that words' meanings arise not from an intrinsic quality that links them to the phenomena they represent, but from the systematic distinctions that differentiate them (as signs or sounds) from one another in a linguistic system (Saussure 1983[1916]). (Words are "purely differential and defined not by their positive content but negatively by their relations with the other terms of the system. Their most precise characteristic is in being what the others are not" (Saussure [1916]1983: p. 651).) This approach was then elaborated in the science of phonology by Roman Jakobson, who examined how the organization of sounds into systems conveys linguistic meaning. In all cases, structuralism proposed two types of relations (syntax/system, metonymy/metaphor, affine/cognate) that, brought into the realm of social structure, suggested attention both to empirical relations of interaction (on the one hand) and relations of structural equivalence – functional substitutability (on the other).

Claude Levi-Strauss (1969[1949]) applied these structuralist principles to the study of social structure in *The Elementary Structures of Kinship*. Here Levi-Strauss examined the structural logics that organize complex patterns of kin relationships by understanding them as formal laws of transfers (as a marriage may be seen as the transfer of a daughter (or son) from one lineage to another). Levi-Strauss went on to focus on *cognitive* structures, but the encouraging results of this work on kinship led to a common enthusiasm for 'structure' in the social sense as well. There were relatively few rigorously structuralist approaches to social structure, however, though we discuss one below.

Structure as Patterns of Concrete Interaction

A second major approach divorces the idea of structure from the abstract notion of an organized society. Instead, it sees structure as concrete patterns of interaction among individual persons that may exhibit greater or lesser levels of organization. These social relationships are also attached to cultural meanings of various sorts – for instance, subjective orientations or cultural narratives. But these approaches tend to be more bottom up, and suggest a plurality of structural elements that may overlap with or without mutual reinforcement.

Structure as Forms of Interaction

This general approach was largely rooted in the work of Georg Simmel. Like Durkheim and Marx, Simmel saw society (or social life) as fundamentally about relations among persons. But he eschewed the structural functionalists' presupposition that society is divided into subparts organized into a (more or less) functional whole or system. Indeed, in his first major work, Simmel (1890: p. 13) challenges the organismic view of society, which sees society as 'an absolute unity.' Rather, this concept of 'society' is 'only secondary to the real interaction of its parts, only a result of it – as much in reality as in conceptualization.' 'The social organism,' speaking loosely, must be understood as but 'a summary expression of the interaction of the parts,' and it is only these parts – individuals – that have vitality. Rather than the process of differentiation leading to simpler and more unitarily defined individuals (as in Durkheim's conception), the true differentiation is internal to individuals who straddle multiple social roles.

As a result, Simmel decoupled the concept of structure from social groups' functional roles in society, and proposed a 'formal sociology' focused on patterns of interaction among individuals. These interactions – continuously broken off and remade – do not necessarily amount to 'actual organization' (1992[1908]: p. 33), nor must they conform to the routines of society's 'service organs' (Simmel, 1897). Thus, 'Society' for Simmel is social interaction among persons "continuously making connections and breaking them off and making them again, a perpetual flowing and pulsing that unites individuals, even when it does not amount to actual organization" (1992 [1908]: 33). Social life consists of the living interactions, constantly being made and remade, that pulse beneath and beyond their 'service organs' (Simmel, 1897). The regularity of these interactions comes from their being stamped from a limited set of forms.

This sociology of forms has been appealed to by some network researchers as an aegis for their own efforts. However, despite his focus on formal patterns like the dyad and the triad (actually terms supplied by his translator), Simmel's use of 'form' had a somewhat different meaning than a geometrical structure. Hoping to extend a neo-Kantian approach to social life, as he had previously attempted for the study of history, Simmel meant to uncover the 'a prioris' for social interaction, which he considered forms. Here he certainly meant to draw on Kant's idea of forms, quite possibly interpreted in the Platonic way of Hermann Cohen, as something structured in the subjectivity of actors – not a pattern of relationships itself. While purely geometric abstractions may be useful sociological tools, they cannot be separated from the complex subjective orientations from which they tend to emerge. These objective and subjective elements coalesce in ideal typical forms of 'sociation' (*Vergesellschaftung*): e.g., exchange, conflict, and super- and subordination.

Most important for the science of social structure was that Simmel, by not proposing a partition (or multiple partitions) of society into subparts bound by relations, was able to see structure as shifting patterns of interaction between individual persons and thereby frame structural analysis as a conceptual tool that could be applied to different types of connections. As he (1955[1922]) explained in *The Intersection of Social Circles*, an individual may stand simultaneously in multiple social groups that overlap with each other at the site of that individual. Society is a web of relationships that is not organized into a unified and harmonious set of structures but into multiple overlapping, often uncoordinated, and sometimes conflicting, ones.

Structure as Configurations of Individuals

This line of research was continued by Leopold von Wiese (1932), in his 'theory of relations' and his 'theory of social configurations (*soziale Gebilde*).' Von Wiese's work was freely translated by Howard Becker, who rendered *Gebilde* as 'plurality pattern.' Von Wiese's configurations or structures were ensembles of social relationships that had a particular form: he argued that there were three main types of configurations: masses, groups, and corporate bodies. These were structures, generally composed of other structures, that were somewhat farther from the individual than their component structures and consequently more abstracted. (Sorokin's (1962) own approach was similar in many ways, emphasizing the components of social organization as opposed to beginning with functional requirements.) The somewhat exciting aspect of von Wiese's work was the implication that one could begin with social relationships and scale upward, first to simple configurations composed of relationships, and then larger structures. This general approach has been used by Tilly (1998), Martin (2009), and Martin and Lee (2010).

Structure as Stories

This type of approach may seem to have a great deal in common with the structural approach of Harrison White (1992), who was concerned with the question of how social formations emerge. White's first book was a recasting of Levi-Straussian kinship structures using permutation matrices. He then applied this rigorous structuralist understanding of social structure to other types of social structure in a pair of important papers, the first of which (White et al., 1976) was very influential for social networks (see below); although the second (Boorman and White, 1976) was more theoretically central, it was more methodologically challenging and hence less influential. (This line of work was continued by Breiger and Pattison (e.g., 1986), among others.)

White went on to formulate a more general approach to social organization, and here he drew more heavily on S.F. Nadel's (1957) perspective with its cultural grounding, which became clear in White's magnum opus, where he posited a strict duality between structural form and cultural narratives. Structural ties are bound by common identities. Each tie exists both as a pair of individuals, as well as an identity – a story about the basis of the tie's solidarity that provides it continuity. Small structures like dyads concatenate to create larger ones as 'ties mesh with stories' (2008: p. 27). The conversations that take place in ties, the shared beliefs or understandings that bind them, link up to those of other ties, presenting the opportunity for those ties to concatenate into larger structures.

A somewhat related approach is seen in Ronald Burt's (1982) *Structural Theory of Action*, though the focus on action takes him more to the Parsonian legacy of a dialogue with economic theories of action. As with White, we start with a focus on the actor who sees social structure sometimes as if it were a jungle gym to be climbed, and sometimes as if it were an undergrowth to be hacked away with a machete. Even more than in the previous understandings, the duality of cultural and structural understandings is one that in no way requires an overarching order; rather, local ordering principles may emerge, but even when they do, skilled actors may choose to crack them.

Social Structure and Social Networks

As the discussion in the previous section makes clear, this approach to social structure often dovetailed, inspired, or turned into social networks research (*see* Social Networks). Scholarship on social networks focuses on the relationships between concrete actors rather than individuals, groups, or roles. Although the foundational theoretical works in social networks research (e.g., Barnes, 1954) envisioned the network as sprawling, connecting, and all-encompassing form, and hence diametrically opposed to the conventional ideas of well-nested social sub-sub-systems and/or groups, networks have often been understood as being a skeletal structure that should reproduce the outlines of social structure conventionally understood. This is, of course, an empirical question, but the challenges to mounting a full-scale social network survey of a population in order to determine the relation of networks to role structures remain daunting.

Conclusion

Social structure has proved one of the most confusing theoretical terms in our lexicon; it tends to be among the most abstract of our concepts, but has implications of solidity. It often seems to connote constraint of individual actions, but is itself nothing but a set of actions. It is regularly counterposed to culture, but just as regularly appears to be simply the second side of the same coin as culture. Perhaps the best that can be said is that it appears to be an idea we cannot do without.

Social Structure: History of the Concept

Charles Crothers, School of Social Sciences and Public Policy, AUT University, Auckland, New Zealand

Abstract

Although the palpably powerful nature of social structures and their effects seems obvious, it has taken social scientists – and particularly sociologists – a long time to develop adequate conceptions that both are philosophically defensible and also lead to empirical research. During the 'golden age' (in the late nineteenth century and for much of the twentieth century) of social structural analysis, rather underdeveloped ideas of social structure were, nonetheless, pressed into highly effective service in analyzing actual structures and this continues. Alongside these actual analyses, more sophisticated understandings have evolved although this area of study is still not adequately consolidated.

Introduction: Basics

Social structure is a concept and term used to capture the collective properties exhibited by social entities and to identify the characteristics of and specify the relationships among their component elements. It is widely considered to be one of the most important concepts/terms in the social sciences and a particularly central concept/term in sociology and important in other social sciences. However, writing on social structure has been scattered, piecemeal, and not particularly cumulative. Strangely, social theorists have been reticent in making their analyses of social structure more explicit (Callinicos, 2007; Crothers, 1996; López and Scott, 2000; Chew and Knottnerus, 2002).

There are at least four primordial images of social structure, which have to be somewhat separately attended to, although for adequate understanding each must be evoked:

Social Organization: Social structure is the concrete relations among concrete individuals and concrete groups, e.g., Networks.

Social Background Characteristics: Social structure is the relations among people sharing the same social background characteristics, or differing in terms of social background characteristics.

Institutional Structures: Social structure is the relations among people, categories, etc. laid down by ongoing organizations and cultural forms.

Underlying (Deep) Social Structures: Social structures exist (somewhat irrespective of the actions of those 'carrying' them) at deeper (and more abstract) levels.

With all these, they both constrain the possibilities for social activity and provide a structured range of opportunities.

The 'Language' of Social and Structure

According to the *Oxford English Dictionary*, Alex de Tocqueville was the first to use the term 'social structure,' followed by Herbert Spencer in 1872 and then references in the 1940s (Meyer Fortes), and 1960s (Claude Levi-Strauss). Perhaps it is a quite definitive indicator that the term really did not begin to be widespreadly deployed until well into the nineteenth century.

William Sewell Jr. (2005) cites Michel Foucault to suggest that 'structure' is a general metaphor and that "such usages originated … in seventeenth and eighteenth century botany, from which they spread to other natural and social sciences." However, Raymond Williams, in his *Keywords* (1983), provides a rather more lengthy account of the linguistic history. The earliest usages of 'structure' in the fifteenth century referred to the process of building. By the seventeenth century, it referred to both the whole product and the manner of construction – the meaning emphasized the inner structure: the arrangements among constituent parts. The term was used about the anatomy, as a contrast to the functioning (or performance), of a body part. In the 1870s, usages contrasted internal arrangements and (surface) decoration. In the twentieth century in linguistics, and then other social sciences, structure signaled an analytical or formal study rather than a comparative/historical or process approach (which had been more appropriate for the study of more familiar European social structures). There are similar complexities in the meanings of related terms such as form and system. He also notes that "much structuralist analysis is formalist in the sense of separating form and content and giving form priority" (Williams, 1983: p. 306).

There is also a somewhat separate history of the concept of 'the social' which is seen to have arisen as a distinctive order or domain of social reality through various eighteenth century discourses, which theorized and reflected on this order. 'The social' outflanked the more usual social categories up to that time: e.g., the polity, stratificational orders, etc. Its death is seen as arising as it is replaced by a virtual reality comprising signs and symbols seemingly detached from material reality. Social structure can be conceptualized as particularly embedded within this domain.

Phases in Development of the Concept:

Each of the successive 'cohorts' of social structural models is schematically outlined in **Table 1**.

The Prehistory of Concepts of Social Structure

There clearly is a 'prehistory' of concepts of social structure. Several writers have drawn attention to the collectivist aspects of social theory in Greek, Roman, Arab, Medieval, and Renaissance thought. After these periods of social thought, a strong individualism was built into the models of the classical political economists (such as the Scottish school) which clearly limited their interest in social structure. However, over the

Table 1 Phases in social structural thinking

Approach	*Time-period*
'Prehistory'	Pre-1890
Founding fathers	1890–1920
British structural–functional anthropology	1920–50
American structural–functional sociology	1950–65
Inter-regnum	1965–75
Structuralism	1975–85
'Process' reconceptualizations	1985–95
Poststructuralism/post-post-structuralism	1995–present

several centuries of the 'Enlightenment Project,' qualified holistic viewpoints of the social also evolved. Nevertheless, one of the major lessons in the history of social thought is that the extraction of conceptions, both which are *social* (i.e., not essentially political, or even economic) and which also involve *analytical*, *scientific* treatment of the collective properties of social entities, are hard won. Moreover, progress at developing working theoretical models of social structure was slow, in some considerable part because of the lack of development of institutionalized traditions of social theoretical work.

In Donald Levine's (1995) treatment of the Hellenic tradition in sociology, he analyses the approach used by Aristotle to study how the good life might be achieved. Although its moral purpose was paramount, nevertheless Aristotle's was a grounded inquiry. It involved examining the natures of these entities and the reasons why they arose. Aristotle identified the three forms of association:

- households (in which people join together for the sakes of reproduction and of self-preservation);
- villages; and
- city-states (to allow expression of discourse about bad and good, and as the culmination of the social life of its components) especially as represented by their constitutions.

Aristotle then analyzed variation among political communities in terms of their internal relationships between governing and subject strata.

"The constitutive elements of associational domains are their role sets and the resources available to them (e.g., husband–wife, parent–child, master–slave, master–inanimate possession relationships in the household, and ruler–ruled relationships in the political community). Responsibilities for each role–position are specified, together with the type of socialization he deemed necessary to cultivate the best qualities required in the carrying out of those responsibilities" (Levine, 1995: p. 118). Aristotle utilized his dataset of the constitutions of more than 150 communities to examine the best sources for regime stability, especially as appropriate to communities of different sizes and socioeconomic compositions.

Various scattered attempts at social structural analysis occurred thereafter. One of the more notable was that of the medieval Muslim philosopher Ibn Khaldun, who produced an interesting sociology of the cyclical variation of social forms in the Arab world. Charles-Louis Montesquieu in the mid-eighteenth century and then Jean-Jacques Rousseau continued the focus on political forms but began to show how these are embedded within broader societal, and particularly geographical, features. French social thinkers saw social structures as things, shaped by laws, arranged into hierarchies, which had development trajectories and were composed of interdependent cultural and social structures.

An historical sociology of the evolutionary development of societies was most developed by the eighteenth century Scottish *philosophers* in their 'Four Stages Theory' of progression of types of society – hunting, pasturage, agriculture, and commerce. This broad framework was extended and deepened by other writers.

Spencer provided the culmination of this framework in his work, based on considerable secondary analysis, the internal processes within societies, and their stages of evolution. Spencer visualized each stage as being denoted by (1) a given degree of differentiation *between* regulatory, operative, and distributive processes and (2) a level of differentiation *within* each process. He saw five basic stages in terms of their complexity: (1) simple without head (leadership), (2) simple with head (leadership), (3) compound, (4) double compound, and (5) treble compound.

Classical Social Structural Analysis

Some general notions about social structure – which C.W. Mills (1960) later termed the 'Classical Tradition' of sociology – gradually developed during the course of the nineteenth century as a by-product of historical studies, although it was also used in political analysis and social commentary, albeit not much connected up with social research in the narrower sense. This model included "… basic conceptions or theories of such matters as social stratification and political authority, of the nature of bureaucracy and of capitalism, of the scale and drift of modern life, of the ambiguity of rationality, of the malaise individual men so often feel" (1960: p. 5). Such classical sociological analyses focus on at least one social grouping set within a wider social formation. These social groupings often have a particular economic role, hold power, or are centrally involved with cultural development or cultural maintenance, such as social classes, estates, broad political movements, or the 'intelligentsia.' The historical trajectory of the grouping: its rise, continuance, and fall are examined together with the grouping's terminology (especially its own names for itself), internal positions, and external boundary maintenance; its economic base, political power, and cultural legitimacy; its demography; its social and ritual life; its relations to other social groupings, and the leadership, organizations, and networks through which it is organized and can mobilize to achieve any common goals. Tocqueville is an early structural analyst who suggested that through their voluntary associating, for joint interests, both publicly and privately, Americans are able to overcome selfish individualism and to create both an active political society and an active civil society independent from the state.

However, such structural analyses were not underpinned by a formal theory. None of the now-recognized Founding Fathers of Sociology had a well-developed and explicit model of social structure, but a semi-implicit model of social structure was

central within the work of each. For Marx and Weber in particular, this particularly focused on class structure.

Marx

The main thrust of Marx's later work lay in understanding the economic machinery of capitalism. His 'sociology' is both embedded within or envelops his 'political economy': Marx saw social life being lived within 'social formations,' composed of various economic, social, and political groupings: especially social classes which shaped the individuals involved with them.

At the center of each social formation is,

> The specific economic form, in which unpaid surplus-labor is pumped out of direct producers, determines the relationship of rulers and ruled, as it grows directly out of production itself and in turn reacts upon it as a determining element. Upon this, however, is founded the formation of the economic community which grows out of the production relations themselves, thereby determining simultaneously its specific political form. It is always the direct relationship of the owners of the conditions of production to the direct producers–a relationship always naturally corresponding with a definite stage in the development of the methods of labor and thereby its social productivity–which reveals the innermost secret, the hidden base of the entire social structure, and with it the political form of the relationship of sovereignty and dependence, in short, the corresponding specific form of the state.
>
> (Marx, 1981: 791)

The State (as the executive committee of the ruling or dominant class) ensured social cohesion and cloaked capitalist society in a blanket of *false consciousness*, which hid the way in which society was organized in the ruling classes' interests.

In addition, Marx depicted the dynamics of the whole formation which centered on the extent to which such social groupings and particularly social classes might cohere sufficiently to exert a social force in their own right. An important difference is that between a *class-in-itself* (not aware of the shared nature of its material interests) and a *class-for-itself* (which is aware of its shared interests and has some organizational capacity for realizing these). A critical element in building the conflict necessary for an eventual revolution is the dissipation of the cloying *false consciousness*, and its replacement with a *revolutionary consciousness*.

In turn, the dynamics of structural change are placed within a much wider historical framework, in which the successive developments of different modes of production are placed within a sequence. In a general way, ancient (slave), medieval (feudal), and modern (capitalist) modes are seen as part of an evolutionary sequence, with the capitalist mode (and perhaps deformed feudal peasant modes) leading on to the subsequent stage of a socialist mode of production. Societal change is seen as driven by the interaction between organizational arrangements in the economy (relations of production) and technology (productive forces).

Weber

Weber's views (see especially 1947) on social structure are more developed than those of Marx, and his theoretical reflections directly pertain to social structure. Nevertheless, Weber does not attempt to develop a full understanding of social structures. Rather, his tools of structural analysis are designed to assist in the analysis of those portions of historical experience, in which he had a particular interest. On the other hand, his work is cast within a very broad comparative and historical range: encompassing study of Western, Chinese, Indian, and Ancient civilizations. A central point is 'methodological individualism' requiring explanations in terms of the involvement of individuals and also need to meet the criteria of providing *objective* as well as *meaningful* explanation.

Weber's approach to social structure, including social classes, is much more flexible than Marx's. A class is seen as any social grouping which shares a similar position within a market (e.g., the labor market), with 'similar position' meaning that its members share similar life-chances. Rather than emphasizing only the economic/material sphere, Weber sees *several* dimensions around which social strata might form: class (concerned with economic matters), party (concerned with power), and status group (concerned with social prestige or honor).

Finally, Weber provided a particularly potent model of organizational analysis (and social structural analysis more generally) with his theoretical model of a bureaucracy. He depicted this as a 'machine' of hierarchically organized 'offices' filled by meritocratically appointed, salaried, careerist 'officials' who are constrained to efficiently tackle their collective tasks within a systematic framework of rules, records, and reporting.

Durkheim

Of the three (major) founding fathers of sociology, Durkheim was the one most seriously concerned with social structure. However, even for Durkheim, the precise term is used only in passing, and references are made more generally to society, and to the social bonds constituting society.

Durkheim was aggressively antireductionist and collectivist in approach. The concept of a 'social fact' was central, and social facts were seen as separate from, and overwhelming the individual.

Social facts are a framework of collectively shared obligations on the individual, involving either 'crystallized' (e.g., expressed in adages or writing) or more diffuse 'social currents.' Usually the collective shaping of a person is internalized and constant pressure is not needed. Such social pressure is felt most when a person resists obligations. This results in conformity to them because social groups or the State upholds them. At a more descriptive level, Durkheim developed a conception of *social morphology* involving accounts of the nature (e.g., size, functions), number, arrangement (e.g., spatial distribution), and interrelations (e.g., modes of communication, movement, and mutual obligation) among the social parts (individual or collective) of a society.

Durkheim clearly postulated that the central conceptual problem on analyzing social structures was its 'division of labor,' and the consequence for the structure's type and level of social integration. Whereas primitive social structures were seen as organized around similarity in their task structures, which was complemented by a tight 'repressive' social control, more complex societies had a division of labor characterized by complementary specialization, and this was then matched by a system of social control which emphasized 'restitution.'

Simmel

Of other sociologists in the 'founding' generation, the work of Simmel has proved to be of lasting significance. Simmel developed a 'formal' sociology (as opposed to sociological treatment of 'content'), in which properties of small groups and social situations were seen to affect the behavior. His approach could allow the compilation of systematic propositions about the operation of social structures. For example, Simmel wrote about the effects of differences in sizes of groups for interaction among their members. The conception of abstracting social content in order to reveal structural similarities across diverse situations also proved to be helpful to later analysts.

Diverse social groups may nevertheless show identical forms of behavior toward one another on the part of individual members – relationships such as superiority and subordination, competition, division of labor, formation of parties, representation, and inner solidarity coupled with exclusiveness toward the outside can be found in the state, in a religious community, in a band of conspirators, kin, in an economic association, in an art school, and in the family. Simmel's imagery of the way in which people in modern societies are complexly related was through cross-cutting social circles, as opposed to the concentric circles of more primordial situations.

Structuralist Approaches

British Structural–Functional Anthropology

Beginning in the 1910s, and maturing in the immediate post-World War I period, a self-conscious analytical approach to social structural analysis was developed by the British school of structural–functional anthropologists. This was begun by Malinowski, but predominantly shaped by Radcliffe-Brown (1957), and later summarized in a wider range of texts (e.g., Nadel's theoretical treatise: 1957). Earlier approaches in which emphasis was placed on the evolution and diffusion of cultural traits were rejected in favor of understanding the current operation of small-scale societies (and later, rather larger African ones). Any social practice was seen in terms of its 'role' within its societal context, which enabled 'Strange' tribal practices to be 'mapped onto' more commonly understood Western concepts. This approach was considerably inspired by Durkheim's views on social collectivities.

There were at least two main strands, with Malinowski endeavoring to reach down to the ways in which societies met the sociobiological needs of their members, while Radcliffe-Brown emphasized a more strictly social structural level of analysis. The latter approach came to dominate in structural analyses but the theme of how individuals relate to social structures reoccurs in later views and debates.

American Structural–Functional Sociology

During the 1950s and 1960s, American sociology was dominated by an approach generally labeled as 'structural-functionalist,' or (retrospectively) to use Mullins's (1973) term as 'Standard American Sociology' (SAS). To a considerable extent, this involved a translation of British structural–functional anthropology into the then-contemporary and larger scale American context. Although the functional mode of explanation (in terms of consequences, especially for environing social systems) continued, as with its anthropological predecessor, the inherent teleology has been later resisted, although functional analyses can still be seen as a useful heuristic approach for generating hypotheses.

There was a strong and consistent attention to the analysis of social structure through concepts such as 'role theory' and 'social system' and others. Another path lays in the development of research tools more appropriate to the investigation of the structures of large-scale societies, especially large-scale surveys. Theoretical and methodological advances often benefited each other. A range of standard social background variables was deployed in surveys, which were useful in predicting patterns of behaviors or attitudes. As Merton (1949) pointed out, these social background variables reflected the main social statuses which people might occupy.

While much of this sociology retained a strong interest in characteristics of individuals (or patterns among various of the properties of individuals) which the survey research methodology made possible, surveys were also employed to study the 'emergent' or 'structural' characteristics of various types of social unit such as groups, households/families, organizations, suburbs, regions, and nations. As well, considerable theoretical and methodological knowledge accumulated about how relations between individuals and various types of social entities might best be studied and explained. A useful example is the Lazarsfeld typology of the different types of individual and collective properties, in which individuals can influence other individuals or collectivities and in turn collectivities can shape individuals or other collectivities.

At a more macrosociological level, analyses of which social dimensions (social cleavages) were more salient in describing patterns of societal development and operation. For example, societies with cross-cutting cleavages were more likely not to be crippled by major conflicts since the widespread sharing of interests held in common by 'parties,' which stood in different positions in relation to a dispute, is likely to dampen its socially destructive effect. Comparative historical sociologists studied questions such as the degree of support for left-wing political movements, finding their explanations in terms of other features of the social structure: for example, lack of socialist development in USA was seen as flowing from the (supposedly) quite open-ended texture of the American social structure, and especially the possibility that upward mobility might be achieved by all.

The 'human ecology' aspects of the 1920s Chicago school of sociology were formalized by Duncan and Schnore into a 'POET' framework, which analyzed the interrelations among Population, Organization, Environment, and Technology (see also Hawley, 1986). This schema usefully pointed to the natural environment context of social structures and some of the key elements which shaped their long-term operations.

Role theory was an important conceptual foundation stone. Often the concept was used generally and descriptively to indicate that social life was socially patterned. In some theoretical approaches, emphasis was laid on the way roles and their occupants were shaped by social learning and monitoring by role-others, rather than as in the 'symbolic interactionist' formulation in which role-occupant's orientation to their role was stressed. Panoply of role-related concepts piled up

(e.g., Merton's status-and-role theory which allowed finer conceptual discriminations).

Parsons

The 'grand theoretical' work of Parsons endeavored to lay down a solid conceptual foundation and standard vocabulary for the social sciences, in particular, anthropology, sociology, and social psychology (e.g., 1973). The three interlinked master concepts – culture, social systems, and personality – are held to be separate, autonomous, and yet interpenetrating analytical systems. A social system is seen as the interaction of the plurality of persons and their relationships, with its central building block being that of the role. Roles are a sliver of someone's personality, but are more than this in that they also stand outside the personality. Roles constitute and govern the interaction between people – each in their respective roles – through providing complementary and mutually adjusting sets of expectations. Many roles are 'institutionalized' by being built into wider cultural patterns and controlled by social sanctions. However, the social system seems to be a residual concept and the cultural determinism is so overwhelming that there is little room left for autonomous social activity.

French Structuralism

During the late 1960s, two forms of structural analysis – both drawing inspiration from Marxism, and both emanating from Paris – captured much attention. Despite their relatively brief span of popularity, both marked out the extremes of a 'structural determinist' approach. For French anthropological theorist Claude Levi-Strauss, "The term 'social structure' has nothing to do with empirical reality but with models built up after it" (1963). Indeed, the drive of his analysis is to show how styles of 'native' thinking (in whichever culture is being studied) across all areas of cultural and social life are all embedded within deep semilinguistic patterns of thinking (possibly even mentalistic, being hard-wired into the digital structure of the brain). Thus, 'native' concepts of kinship patterns, religious ideology, and all else is subsumed under broad models of thinking that eventually reduce down, via transformation rules, into dualities dwelling in the mind. Levi-Straus's approach showed mind-stretching linkages, such as postulated themes running through the entire range of North American tribal cultures, but it seemed to falter in the hands of others.

The other structuralist development, which peaked at much the same time, was centered on the work of social philosopher Louis Althusser. In this approach of 'structural Marxism,' Marx was (re)interpreted to fit a highly determinist and scientific understanding of social development. Marx's model of the working of the capitalist economy was accepted as adequate and instead, attention focused on two consequent issues:

- How Marxism might be construed to offer satisfactory explanations of societies other than capitalist ones (and indeed to provide a theorized sequence of types of society)?
- How the whole of a society was to be seen as operating? A threefold distinction is assembled: society is seen as comprising the economy, the polity, and the ideological state apparatus. The functional role of the latter two sectors is to repress the population, by force and by imposing ideological consensus, into supporting the status quo set by the current mode of economic organization. A society can be described by which of the three structures is dominant; but no matter which is the dominant structure, it is always the economic structure that determines which is dominant: the economy is the determinant 'in the last instance.' In capitalism, the economy is the main institution, whereas earlier societies had been dominated by the family, or in feudal times by political and religious institutions.

Structuralism: 'Standard American Sociology' Supplemented

By the late 1960s and early 1970s, the conceptualizations used in SAS had not only begun to wane in popularity, but they were also directly attacked. Microsociologists were concerned that SAS required too formal and reified a view of people's relationship to the social structure: an 'oversocialized' conception of mankind. On the other hand, the Standard American social structural analysts were criticized for dealing with trivia, for ignoring major societal level phenomena outside the framework they were working within, for lack of any historical or comparative perspective, and for an implicit conservative support of the status quo. To overcome these limitations, the next period of development tended to emphasize structural approaches.

Conflict Theory

The critique of SAS as being overly concerned with 'consensus' was consolidated for a decade or so through the development of a supposedly polar opposite 'conflict' view: a 'soft-core' Marxism, or rather a 'left-Weberianism' whose proponents include Simmel as a fore-runner, Lewis Coser, Ralph Dahrendorf, and John Rex (e.g., Dahrendorf, 1968). This conflict, in contrast to the previously predominant emphasis on consensus, was useful for mobilizing alternative biases, but the distinction proved difficult to sustain over the longer term as it became realized that the two approaches could be seen as essentially complementary, sharing an underlying view of social structure.

The Social Construction of Reality

Berger and Luckmann (1967) developed in the late 1960s a sophisticated account of the 'social construction of reality' which outflanked and advanced the treatments then available. They emphasized the fragility of social reality and the involvement of people in constructing those very social structures, they then came to experience as solid and real, with mechanisms to cover-over any broaches in their facticity, including the sharing of experiential commonalities, the deployment of aphorisms and sayings, and then relating any remaining difficulties people had in fitting into their constructed reality, to broader underlying conceptualizations shared in that culture. This approach points to the major role of legitimating cultural structures, such as religion, which serve to secure the social structure.

Symbolic interactionists and kindred microsociologists tended to remain restricted to situational rather than structural

analyses, but some attempts were made to explore compatible links with more macrosociological topics purveying the general idea that larger social structures involve an often-fragile 'negotiated order,' in which the various groupings involved participate on an ongoing basis (e.g., see Maines, 1991).

Formal Sociology: Blau's Attempted Synopsis and Program

In 1975, Peter Blau organized a group of eminent social theorists to directly confront the concept of 'social structure,' including several involved in historically orientated or comparative studies, as well as those more inclined to survey and other quantitative work. Blau's definition is that "Social structure refers to the patterns discernible in social life, the regularities observed, the configurations detected."

Blau's own program of structural analysis is termed a 'primitive theory of social structure' which pursues a program of 'radical structuralism' which sticks to sheer objective structural features while culture is seen as irrelevant. (See also the extreme views of Mayhew (1980/81) concerning structure.)

Porpora (e.g., 1987) attacks this position by denigrating the deductivist philosophy of science at the heart of structuralist sociology. Rather, an alternative Marxian view of social structure is advanced which explores the relations between a realist and a social constructionist view.

Theoretical Reflections

In addition to these various alternative models of social structure, more specific conceptions were also explored.

- Network theory.
- Organizational Sociology.
- Social Movement theory.

The SAS approach has continued (and has continued to develop) within Sociology (especially in North American sociology), and many social science journals remain filled with studies carried out within its broad paradigm. A common rhetoric shared by many of these more sophisticated versions of SAS cleaves to the formalization, mathematical, and statistical aspects of social structure. For example, White (2008) develops an abstract and difficult conceptualization of social structure, which complements the treatment of network linkages with an extension into the cultural aspects which also shape them.

Kontopoulos (1993) developed a whole series of models of social structure in which their central logic is laid out cleanly to be inspected, leading to the argument that the model of 'heterarchy' is most appropriate for capturing the complexities of hierarchy and feedback so rife in social life.

Under the leadership of Alexander (and in the writing of several important Continental social theorists, including Habermas and Luhmann), a 'neofunctionalist' revival attempted to reclaim much of the theoretical territory earlier dominated by Parsons through the addition of a theory of group formation and conflict (Alexander, 1985, 1987).

David Lockwood (1992) also revisited Parsons's earlier work on the differences between integration at the systems level and integration at the social level. He carefully reviews the relevance of Marxian and Durkheimian theories, each with their dominant and supplementary contributions in providing explanations at both these levels, and indicates how they might be combined.

'Process' Reconceptualizations of Social Structure

By the late 1970s, the critique of ideas about social structure had turned in a much more strictly theoretical direction, although this assisted in the demise of interest in 'social structure' because it became detached from concern with social issues. One line of theoretical debate focuses on the relationship between the macro- and microlevels, while another angle on it concerns the relationship between agency and structure.

The 'figuration' word picture provided by Norbert Elias pointed to "The network of interdependencies among human beings is what binds them together." But two major theorists have brought out in-depth discussions of social structure: Bourdieu's 'social constructivism' and Giddens's 'structuration theory.'

Bourdieu has developed a sophisticated and appealing imagery of social structure and has connected this up with a wide range of empirical studies of particular social structures. His analysis works between the collective and individually based concepts, and between the subjective and the objective and in a correspondingly mediating position in terms of the other antinomies. Key concepts include 'habitus' (the mental schemas that people employ to order their world and which shapes their actions), 'capital,' and 'field': although these key terms are supplemented by many others.

In a series of theoretical works stretching from the mid-1970s, Anthony Giddens (e.g., 1984) has developed the most sophisticated generally available theory of social structure, usually advanced under the banner of the theory of 'structuration'. Giddens is less concerned with developing a conceptual framework, which would then allow the derivation of more specific theories, than with endeavoring to recover from the available stock of social theories, a vision of social structure which can be philosophically sustained.

In reaction to Giddens's somewhat mystical rendering of the linkage between agency and structure, Margaret Archer (e.g., 2003) has championed a 'morphogenetic' approach, drawn in part from earlier theorists and general systems theory, in which the various levels and phases and types of consequence are explicitly spelled out. In this approach, structure and action operate over different time periods, with structure leading to action which may have the consequence of structural elaboration. More recently, this approach has been developed by a book on the relations between culture and social structure, and another on social structure.

Sewell (2005) recognizes the untrammeled cognitive power of the concept of social structure, and sees it as afflicted by the three problems of appearing too hard, too impervious to change, and too open to a variety of meanings (in particular, the difference between the 'social structure' and 'cultural structure'). He seeks to clean up the concept from these three contaminants. He uses the work of Giddens and Bourdieu to endeavor to provide a sense of agency and thus overcome the too rigid immutability of social structure; explores the potential for providing an account of social change; and stresses the

involvement and interpenetration of both culture and resources within his concept of social structure.

Mouzelis (e.g., 1995) has been involved in a program of theoretical work to reclaim the centrality of sociological theory from the clutches of philosophy, doctrinaire Marxism, or culturalist idealism into which it too easily has recently fallen. Central is the hierarchy of social levels, and their myriad connectiveness. Giddens's concept of 'dualisms' is opened up when he points out that people vary in their relationship to the social structures they are in: sometimes being involved with merely reproducing the social structure while at other times standing off from it. He attempts to breakthrough the usual demarcation drawn between the micro- and the macrolevel by suggesting that some apparently microsituations have important macro-consequences. Analysis, he argues, should also concentrate as much on social integration as systems integration.

On the whole, Bourdieu's schema seems rather more satisfactory sociologically, than that of Giddens. Whereas Giddens's 'memory traces' seem quite psychological, Bourdieu's 'habitus' is clearly not only shared across each of the different groupings (e.g., classes), but further is an instrument of social differentiation in that different social groupings have different habituses: they are often complementary to each other within a wider system. Bourdieu's main drawback is that his analysis exudes a mysticism, which is not carefully exercised from his conceptual thinking. Other commentaries abound, but alternative theoretical programs developing these 'process reconceptualizations of social structure' have yet to gain any momentum (Elder-Vass, 2012; López, 2003; Parker, 2000).

More recently, some postmodernist writings (e.g., Baudrilliard, 1983) have challenged structural analysis as an explanatory approach, essentially by declaring that the subject-matter it is concerned with has evaporated under a deluge of simulacra and electronically borne imageries. The stronger version of postmodernist arguments can be that people's choices are so socially unconstrained that they are located merely in a 'statistical mass' (or even 'random mass') devoid of social control (although, an alternative argument is that the extent of cultural control through media and cultural images is overwhelming). The weaker version of this argument posits that the hold of modern social structures has loosened, and that the opportunity space of people's choices has so widened that the standard verities of sociology have lost their explanatory purchase. No clear empirical support for this viewpoint is adduced, and it is arguable whether this critique is able to be arbitrated by empirical research. In the absence of clearer empirical support, it seems reasonable to suggest that the 'end of the social' argument tends to have been painted in too brilliant hues. Indeed, the death of the social has been much exaggerated.

The most recent approach to analysis of social structure is that of 'analytical sociology' (e.g., Hedström and Bearman, 2009) which sees social structures as emerging from particularly social mechanisms that operate at an individual level, although buffeted by the social interaction contexts of the people involved. A discrete – but considerable – array of such mechanisms have been identified, although it remains unclear the extent to which this approach allows adequate analyses of social structures at the more aggregate or collective levels.

Conclusions

Conceptual debate concerning social structure has most importantly developed in sociology, together with attendant social philosophy but an interest in, and use of, the concept is spread across the other social sciences, but without raising further issues. Anthropology has a lively discourse, especially about the relationship between culture and social structure and Geography and Political science (but also economics and social psychology) all actively deploy the concept in many empirical analyses.

The task of pinning down the best way to conceptualize social structures continues to slowly advance. If the way ahead is not clear, certainly lessons can be derived from reflecting on the history of social structural analysis noting several common difficulties that any schema needs to be concerned with:

- It seems useful to quite clearly separate social structure both from its (external) causes and its effects.
- As well as seeking understanding of how a social structure operates, it is important to ground this understanding in the ongoing everyday life of members, and also to contextualize the social structure in terms of its long-term tendencies, and its relations with other social structures.
- Particular care is needed to link micro (e.g., the interactional order) and macro aspects of social structures, and it is particularly important to capture both the determined (structure) and the voluntaristic (agency) aspects of social life.
- Another distinction which may be helpful is that between culture and social structure, which certainly must always be addressed.

Social Studies Education

Antonio J Castro and Ryan T Knowles, University of Missouri, Columbia, MO, USA

Abstract

The field of social studies education encompasses a variety of perspectives about the nature of social studies subject matter and its goals. This article traces twin aspects of social studies education: social studies as social science and social studies as social education. Scholars who see social studies as social science education view the field as incorporating the disciplinary concepts, knowledge-based, and strategies of a variety of unique disciplines (history, geography, economics, etc.). Those who advocate for social studies as social education place civic and democratic teaching as central to the goals and outcomes of social studies. Both approaches, however, serve to prepare youth to engage in an increasingly complex and diverse global world.

The term 'social studies education' originated in the United States as part of the 1916 report of the Committee on Social Studies for the Commission for the Reorganization of Secondary Education (Lybarger, 1990). Since its inception and the 1917 founding of the National Council for the Social Studies – an organization created to advocate for social studies education – tension and conflict continue to surround the meaning and purpose of 'social studies education' (Evans, 2006; Saxe, 1991). Jack Nelson (2001) explained, "Defining social studies is not an easy task; it is encumbered by a confounding history, conflicting conceptual ideas, and strong ideological divergence in both political and educational philosophy" (p. 15). For some, social studies education acts as an umbrella of various disciplines, such as history, geography, economics, and political science. For others, social studies education embodies a unique attention to the social and civic aspects of schooling and learning. Stephen Thornton (2008) labeled these two general approaches as social studies for social science and social studies for social education. In this article, we review concepts and ideas related to these two aspects of social studies education and suggest that these stances have the overlapping goals of preparing youth for later social and civic life.

Before we proceed further, we must address the international scope of social studies education. Keith Barton and Patricia Avery (in press) noted that internationally the term 'social studies' may have little significance to educators in different countries. In some countries, history and geography are taught independently of each other. In others, the terms *civics*, *social education*, and *social sciences* are used often to describe various coursework that could be considered 'social studies' in the American context. Furthermore, international research indicates that different purposes and meanings of history-centered teaching and/or social education occur given the context of each country and its political and educational school systems. For example, international researchers have found that history education and civic ideas are based on their unique national contexts (see Barton, 2001; Ho, 2010; Levstik and Groth, 2005; Pike, 2000). Regardless, the concepts discussed in this article will have relevance to a wide range of educators and researchers across the globe.

Social Studies as Social Science

The stance that social studies represent a variety of disciplines embodies a set of key assumptions. First, this approach grants each discipline (history, geography, economics, political science, etc.) its own status as an academic pursuit. John Braxton and Lowell Hargens (1996) described important characteristics of an academic discipline: codification or consolidation of knowledge into specific domains, paradigm development, and consensus thinking – both of the later describing common theoretical and disciplinary habits of mind. Second, this view holds that students in various levels of schooling can acquire foundational aspects of each discipline. American curriculum theorist, Jerome Bruner (1960), in his *The Process of Education*, proposed that "Any subject can be taught effectively in some intellectually honest form to any child at any stage of development" (p. 33). In order to accomplish this task, Bruner asserted that each discipline had a certain base structure, which included analytical skills and habits of mind or orientations used to construct and solve problems. Through the use of spiraled curriculum, children could engage in different aspects of the structure of the discipline without necessarily needing to focus on the accumulation of facts. Finally, this approach positions the 'social studies' as a loose label meant to group these disciplines around their general focus on understanding social life.

Here, we discuss the research and ideas related to three disciplines: history, geography, and economics. Given the assumptions listed above, the approach taken to the teaching and research of these areas relies first on identifying a set of domain-specific knowledge, techniques, or analytical skills. Second, scholars and educators then attempt to uncover the practices, challenges, and influences on the learning and teaching of the discipline.

History Education

Much of research in history education arose in the United Kingdom in the 1970s and 1980s at a time when curriculum reform efforts in history centered on teaching youth disciplinary concepts and skills related to history (Barton and Avery, in press). Later, work in the United States and Canada followed

suit in tracing the ways in which students interpreted historical events and thought about evidence (Barton, 2008).

In investigating history education research, scholars first established certain parameters of domain-specific knowledge. VanSledright and Limon (2006) described two kinds of knowledge related to history learning: substantive knowledge and procedural knowledge. Substantive knowledge includes both conceptual and narrative ideas about what happened in the past and overarching themes and trends that occur in historical accounts. Procedural knowledge relates to the knowledge of how to research and interpret the historical past, using a variety of analytical skills and tools.

In addition to knowledge, scholars also asserted a set of habits of mind employed by historians to solve problems of interpreting the past, called historical thinking. Levesque (2009) explained the difficulty of historical thinking,

> Historical thinking is, indeed, far more sophisticated and demanding than mastering substantive (content) knowledge in that it requires the acquisition of such knowledge to understand the procedures employed to investigate its aspects and conflicting meanings…To think historically is thus to understand how knowledge has been constructed and what it means. Without such sophisticated insight into ideas, peoples and actions, it becomes impossible to adjudicate between competing versions (or visions) of the past (p. 27).

Hence, historical thinking embodies the processes by which a historical account is constructed from various pieces of evidence. Scholars have identified different aspects of historical thinking, including historical evidence, continuity and change, progress and decline, historical empathy, and historical agency (Barton and Levstik, 2004; Levesque, 2009; VanSledright, 2011; Wineburg, 2001). Skills in evaluating historical evidence would encompass analytical techniques to determine the appropriateness of the source, its original purpose, its context, and any world assumptions or biases of the author of the source, as well as corroborating its information with other sources (Levesque, 2009). On the other hand, historical empathy implies the ability on the part of the historian to understand the context of the actors. According to Barton and Levstik (2004), historical empathy embodies a caring aspect as well as perspective recognition. In the latter, the historian must acknowledge a sense of normalcy in the everyday actions of those living in the past – even if these actions or mores seem inconsistent with the current context of the historian. Exhibiting historical empathy can be difficult for youth and students to grasp (Brooks, 2009). Historical thinking skills and specific domain knowledge have been at the base of research on the teaching and learning of history (Barton, 2008; Hicks et al., 2012; VanSledright and Limon, 2006).

Research in history education addresses a variety of different aspects of how youth come to understand and make sense of historical concepts and tools. For example, VanSledright (2002) documented how he taught a historical inquiry-based unit in a fifth grade classroom and how students responded to this instruction. Wineburg and colleagues (1997, 1991, 2001) investigated how different background knowledge affects the way teachers approach the teaching of history, differences between high school students' conceptions and use of historical interpretation as compared to that of a professional historian, and differences across gender in their construction of important historical events. Terrie Epstein (2009) captured how African-American high school students interpreted American history differently from their White counterparts. Likewise, Porat (2004) discovered that Israeli students' cultural memory (either conservative or more liberal) influenced their reading of history texts. These are but a few studies of a myriad of studies on the teaching and learning of history.

Geographic Education

Like research done in history education, scholars in geographic education investigate the teaching and learning of domain-specific skills and ways of thinking associated with the discipline of geography. In the United States and several countries, geography instruction has revolved around the teaching of the five themes of geography (Schoenfeldt, 2002). These themes include the concepts of location, region, place, human–environment interaction, and movement. The idea of location encompasses the absolute location of an area based on longitude and latitude lines and relative location, a more general description of where an area is situated and its surroundings. Region describes an area based on a particular physical characteristic (mountainous, river valley, tundra, etc.) and/or a human-made characteristic (political regions, cultural regions). The geographic idea of place describes both the human and physical aspects of an area that give it a distinctive feeling or atmosphere. The rise of place-based education in geographic education builds on the notion that if students interact with a place (e.g., visit a wildlife preserve or forest) they will be more environmentally conscious (Resor, 2010). Human–environment interaction refers to the ways in which human beings are affected by, adapt to, and change the environment. Finally, movement relates to the movement of people and goods through transportation and the movement of ideas through communication.

While the five themes capture a variety of ideas in geography, geographic literacy includes more specific processes. In the United States, the report of the Geographic Education National Standards Project (1994), *Geography for Life*, laid the foundations for geographic skills and ways of thinking that should inform the scope and sequence for geography education in the public schools. This report outlined a matrix of skills that include understanding the world in spatial ways, distinguishing places and regions, identifying unique physical and human systems, relating how environment and society interact with each other, and knowing the varied uses of geography (Hume and Boehm, 2001).

Barney Warf (1999) described the research in geographic education as a varied enterprise. He wrote, "Because education is an enormous, diverse, and complex set of tasks, ranging from instructing students with disabilities to curriculum design to outcomes assessment, the literature in geography inevitably mirrors the school of that project" (p. 587). Despite its wide scope, a few central concepts have dominated much of the research in geography education (VanSledright and Limon, 2006; Segall and Helfenbein, 2008). Research studies have focused on what children and youth know and understand

about geographic concepts. For example, Hickey and Bein (1996) identified concepts like location and directionality that are difficult for primary grade students, ideas like landforms and latitude versus longitude that pose challenges for intermediate grade students, issues of cultural geography and climate that middle grade students struggle with, and skills with decoding graphs representing climatic information and physical geography related to plate tectonics as challenging to high school students. Other studies traced how students come to understand the different themes of geography (Trygestad, 1997). One study by Thomas and Willinsky (1999) compared mental maps of the Pacific Ocean region drawn by students in 11 countries and two US states, finding that although students differed, students shared similarities in their mapping, suggesting that they believed that those living in the Pacific Ocean region had geographic, if not cultural, closeness with each other.

In addition to this research, several studies focus on the geographic knowledge and preparation of teachers. For example, British scholar Walford (1996) classified four ways that teachers viewed geography: *interactionists*, which stressed the interdepenendence of humans and their environment; *synthesizers* who utilize various disciplines in the study of the earth; *spatialists* who study the distribution, relations, processes, and consequences of geographic resources; and *placeists* who focus physical geography and the location of places and regions. Despite these orientations, however, Catling (2004) discovered that among the 218 elementary teachers surveyed, most participants defined geography as limited to the learning of facts, names, places, and physical aspects. Indeed, researchers have lamented over the incomplete preparation and knowledge-base of teachers in terms of geography (Segall and Helfenbein, 2008).

Finally, research in geography education also investigates the role of curricular policies and contexts on the teaching and learning of geography. Of recent concern, the move toward standardization and accountability poses threats to the teaching of geography, especially when geography subjects and social studies may not be tested (Segall and Helfenbein, 2008). Robert Bednarz and Sarah Witham Bednarz (2008) noted, "Geography runs the risk of becoming the 'subject left behind,' especially in today's politically conservative environment in which history is privileged among the social sciences" (p. 24). Other challenges, such as limited space in the curriculum and the lack of technology needed to explore tools such as Geographic Information Systems or computer-assisted cartography, continue to be pressing concerns for scholars (Segall and Helfenbein, 2008).

Economics Education

Like geography and history, economics education centers on a specific base of disciplinary concepts and skills. In 1995, the Joint Council on Economics Education in the United States published a final revision of the *Framework for Teaching Basic Concepts* in economics (Saunders and Gilliard, 1995). This framework included 21 concepts divided into four major categories. The first category, fundamental concepts, incorporated ideas such as scarcity, productivity, incentives, and opportunity costs. The next two categories, micro- and macroeconomics, included a variety of concepts that affect national and global economics, such as markets, supply and demand, exchange rates, interest rates, fiscal policy, and income distribution. Finally, international economics, the fourth category, introduced students to the topics of comparative advantage, barriers to trade, balance of trade, and economic growth. Although this concept-based approach appears relevant in the US contexts (Walstad, 2001), Miller and VanFossen (2008) noted that others scholars have provided different models to define economic literacy, or the ability to think like an economist. For example, Dahl (1998) characterized economic literacy as encompassing these six key ideas:

- There is no such thing as free lunch.
- Thinking incrementally.
- Markets coordinate consumption and production.
- Relative price changes guide decision-making.
- Trade promotes growth.
- Markets can fail.

Regardless of challenges to the concept-based model, the rise of standardized testing in the United States and the push for economics education as a stand-alone course has led to the dominance of the concept-based model to guide precollegiate economics education (Walstad, 2001). However, internationally, countries like the United Kingdom (Davies and Durden, 2010) and Korea (Hahn and Jang, 2010) see much less emphasis on economics as a subject for study among high school students. Instead, economic themes or principles are interwoven into an already crowded curriculum. So, variation across international educational contexts, governmental policies, and education reforms will greatly affect economics teaching and learning opportunities for students in schools.

Like geography education, the research in economics education appears varied and complex. Early foundational research into children's economic thinking began in Italy with the work of Berti and colleagues (Berti and Bombi, 1988; Berti, 1995). These studies explored children's conceptions of banking and monetary systems. Later studies of children's economic reasoning adopted a Piagetian stage development approach whereby children's understanding and misconceptions of economic principles become more sophisticated as they progress developmentally (Miller and VanFossen, 2008). Research among high school aged students explores various attitudes about economics (Phipps and Clark, 1993; Walstad and VanScoyc, 1990), students' background knowledge and competency (Becker et al., 1990; Walstad and Rebeck, 2001; Harris Interactive, 2005), and degrees in which students engaged in economic reasoning (Miller and VanFossen, 1994; VanFossen, 1995). A few studies have investigated the role of various instructional models, like problem-based learning, on economics education (see Son and VanSickle, 2000).

The stance that views social studies as social science has produced significant insights into the learning and teaching of various social studies subjects. Barton and Avery (in press) reminded scholars that any investigation, whether historical or geographical or economical, will always borrow from the key concepts of other disciplines. For example, how can a historian understand a civil war without understanding both the geographical and economic concepts of the time period?

Social Studies as Social Education

Unlike social studies as social science, social studies for social education views the purpose for teaching as preparing youth for their later participation in adult life and citizenship. Indeed, many, if not most, educators view the purpose of social studies as promoting the knowledge and skills necessary for civic participation (Barton and Avery, in press). Even with such strong support, education for citizenship can vary tremendously depending on the context of the school, teachers, and students. A leading researcher in international citizenship education, Carole Hahn (1998) asserted, "there is no one form of democracy and there is no one way of teaching democracy" (p. 236). As a result, many conflicts exist in relation to the role of social studies to promote citizenship.

Joel Westheimer and Joseph Kahne (2004) identified three kinds of citizens promoted in schools. First, the personally responsible citizen works and pays taxes, obeys laws, and is generally responsible within their community. In a crisis, these citizens may donate money or materials necessary to alleviate the problem. Secondly, a participatory citizen has an active orientation that works to organize their community and influence government policy toward the common good. During a crisis, these people are likely on the front lines organizing and collecting goods. Lastly, the social-justice-oriented citizens critically assess social, political, and economic structures to understand root causes of social problems. These people ultimately seek out avenues for change at the societal level. Westheimer and Kahne believed that democracy requires all three types of citizens; however, the participatory and social-justice orientations contribute the most to democratic societies.

Research on students focuses on views of citizenship and democracy. Large-scale international surveys demonstrate widespread student support for democratic values, such as free elections, strong civil society, women in politics, and freedom of speech (Torney-Purta et al., 2001; Schulz et al., 2010). In contrast to these findings, other research shows that students generally support 'thin' conceptions of citizenship similar to the personally responsible citizen described above. Students are very likely to anticipate voting, but less likely to anticipate taking part in more active political behaviors, such as collecting money, gathering signatures on a petition, protesting (legally or illegally), joining a political party, engaging in local politics, or expressing opinions in newspapers (Cleaver et al., 2005; Kennedy, 2007; Schulz et al., 2010). The discrepancy between support for democratic ideals and the lack of action to support such values necessitates education to encourage more participatory and social-justice citizenship orientations. Thus, social studies education attempts to address this disparity.

Conflicts in Citizenship Education

Within the United States, Diane Hess (2009) differentiated between civic education, which relates to *fitting in* to society as it currently operates, and democratic education, which emphasizes the dynamic and competitive nature of democracy. Walter Parker (2008) advocated for education for *Enlightened Democratic Engagement*, which incorporates active political engagement with both democratic values, such as rejecting unjust laws, fighting civic inequality, and cooperating with others regarding public policy. However, coming up with an ideal goal of citizenship education is much easier than developing schools that produce an ideal outcome. Not surprisingly, differing views on how to promote democratic citizenship education exist.

In practice, Barr et al. (1977) identified three civic outcomes related to the social studies. First, education for social transmission emphasizes fixed core knowledge and skills for students to learn and believe. Thus, education serves to reproduce society, as it exists, leading to passive civic behaviors and attitudes. Secondly, social studies as social science seeks to give students skills necessary to understand human behavior using social scientific methods inherent to anthropology, political science, historiography, and/or geography. The goal is for students to gain the ability to evaluate the world removed from subjective views based on biases or prejudices. Finally, education for reflective inquiry is based on students' self-selections of problems and working toward resolution. Through reflective inquiry, students gain the skills to explore issues relevant to them and ultimately address real social problems.

Criticisms of the three forms of citizenship education above focus on two key aspects. First, the frameworks discussed fail to address issues of group membership and identity, such as structural inequality, sexism, and LGBTQ issues. Secondly, the emphasis on the nation-state in traditional citizenship education neglects increasingly important global perspectives. Marianna Papastephanou (2008), a scholar in Cyprus, strongly argued that traditional notions of citizenship education, similar to the descriptions of Barr and colleagues, fail to provide views of society distinct from what already exist. Such views serve to promote the perpetuation of current political and social realities. Papastephanou called for an enlarged view of citizenship that goes beyond narrow considerations and allows for conceptions that are radically different from current society.

In response to the shortcomings of popular conceptions of citizenship education, various critical discourses promoting social justice have become more prominent (Bickmore, 2008; Tyson and Park, 2008; Knight Abowitz and Harnish, 2006). T.J. King (2012) asserted that education for social justice requires addressing authentic community needs, fostering democratic citizenship focusing on addressing current unjust conditions, attending to marginalization, humanizing the other, starting from lived experience, and cultivating critical attitudes. Such perspectives in education can serve to create avenues for addressing structural social, economic, and political inequalities, thus promoting a democratic society.

In recent decades, globalization has led to increased intercultural communication, transnational identities, and international environmental political issues (Merryfield and Duty, 2008). As a result, citizenship scholars work to incorporate global perspectives while maintaining local heterogeneity (Linklater, 1997; Pike, 2008). To address this tension, leading scholars in international education, Patricia Kubow et al. (1998), advocate multidimensional citizenship education. Such an approach involves four dimensions which include a *personal* dimension focusing on socially responsible habits of mind, heart, and action; a *social* dimension focusing on building civil society by placing importance on a commitment to action based on respect for the rights of others; a *spatial* dimension addressing overlapping identities (local, national,

regional, and global), while acknowledging the interplay between diversity and regional uniqueness; and finally a *temporal* dimension focusing on issues of citizenship regarding variations across time.

In short, social studies researchers emphasize the need for curriculum to move beyond the transmission of traditional civic behaviors to youth. Newer models of civic education focus more on active civic engagement with consideration of the multicultural and global realties of their society.

International Perspectives

International research on education for citizenship education centers on the development of *civic competencies*, or the role of education in developing political knowledge, skills, and attitudes (Hahn, 2010, 1998; Ehman, 1980). Early research based on theories of political socialization traces the influence of family, school, and media on the political views of youth. However, recent research takes a more constructivist stance and views students as active constructors of meaning, opposed to simply passive recipients of messages (Torney-Purta et al., 1999, 2001; Wilkenfeld et al., 2010; Beaumont, 2010). While a complete overview of international and comparative education is not feasible for this work, several major trends exist.

First, international researchers strive to build an understanding of a democratic school (Davies, 1995; Davies and Kirkpatrick, 2000; Davies et al., 2002, 2005; Trafford, 2003; Harber and Mncube, 2012). Clive Harber and Vusi Mncube (2012) summarized the discussion by stating that a democratic school should make a clear commitment to values of education for democracy, such as regular, free, but polite exchange of views and opinions. The structures and practices within a school involve significant sharing of power and decision-making between staff, students, and parents. Moreover, a democratic school culture should be characterized by relationships built on trust and respect, therefore avoiding corporal punishment along with any form of physical punishment and bullying. Breaking down these barriers allows students to experience a democratic atmosphere to build their capabilities for future civic engagement.

Second, researchers investigate classrooms that support an *open classroom climate*, which is commonly associated with fostering civic competencies. Hess and Avery (2008) referred to such climates as having a 'democratic ethos,' by allowing open disagreements and diverse opinions within the classroom. Avery and Simmons (2008), studying students from the Czech Republic, Lithuania, and Azerbaijan, discovered that using a technique called 'structured academic controversy' led students to feel more interested, engaged, and encouraged to express their own views. In South Africa, Finkel and Ernst (2005) concluded that revised curriculum focusing student and issue-centered pedagogy had a strong and positive relationship with student civic/political knowledge. Moreover, an open classroom climate has demonstrated a positive relationship with positive civic attitudes and potential for political participation in a variety of countries including the United States (Torney-Purta et al., 2001), Chile and Portugal (Torney-Purta and Amadeo, 2004), and Israel (Perlinger et al., 2006).

Finally, an emerging trend of international citizenship education research focuses on the role of Western democratic values in non-Western countries. A leading scholar on Asian citizenship, Kerry Kennedy (2004) called for an exploration of the compatibility of local and Western values with the hope of developing indigenous notions of citizenship. Cross-national research studies support the influence of traditional values on civic orientations. For example, East Asian notions of citizenship graft themselves to older values such as moral behavior in public life and welfare of the community over individual rights (Kennedy and Lee, 2014; Kennedy and Fairbrother, 2004: p. 294). These traditional values, inherent to Confucian tradition, may potentially negate harmful effects of rampant individualism common in Western democracy (Kennedy and Lee, 2008). Studying South African and Kenyan students, Kubow (2007) explored South African and Kenyan teachers' beliefs about democracy and concluded that their beliefs were informed by both global/Western rights-based civic conceptions and local/indigenous values of compassion, communalism, and concern for the interests of the community. Within Israel, Orit Ichlov (2005) noted tremendous differences between expected political participation between students in Hebrew state schools, Hebrew religious schools, and Arab schools. As such, conceptions of citizenship vary based on cultural contexts.

Social studies as social education attends to how schools can give students capabilities to support a democratic government and society. The research in this area addresses the interaction of local contexts and the influx of ideas through globalization and other forms of pluralism as they relate to civic and democratic education.

Teaching Practices for Social Studies Education

Several approaches exist for teaching in social studies to students and youth. These include strategies that incorporate problem-based learning, discussion of controversial events or situations, historical investigation, authentic pedagogy, simulations, and multimedia rich instruction. Here, we outline three strategies that are popular in the social studies research literature: inquiry-based learning, the use of Socratic seminars, and academic structured controversy.

Inquiry-Based Learning

Sometimes referred to as the historical inquiry method, this approach to teaching social studies content recently became even more popular in the United States with the publication of the *College, Career, and Civic Life (C3) Framework for Social Studies* in 2013, which promoted inquiry-based learning as the heart of social studies instruction. The process includes four basic steps. First, students with the help of teachers construct inquiry-based questions about a topic that is under investigation. These questions ought to be thematic or broad in scope. Second, students apply domain-specific strategies (e.g., historical thinking, geographic thinking, etc.) to investigate a variety of primary and secondary resource materials. Third, students interpret the data to construct responses to their original inquiry question. Finally, students communicate their findings with others through writing, advocacy, or activism. This final step enables students to

make their new knowledge base relevant to their classroom and/or local community. In the inquiry-based learning approach, teachers act as facilitators and provide useful resources to guide students' investigations.

Socratic Seminars

Social studies researchers advocate seminar discussions to focus on improving understandings of an issue at hand (Hess, 2009; Parker, 2008, 2010). In order to set up a seminar discussion a teacher must first establish classroom norms that work to encourage respectful discussion between students based on the prompt, while also deemphasizing the teacher as the centerpiece. Walter Parker (2004) suggested starting with a powerful prompt such as a text, film, artwork, or political cartoon. Subsequently a teacher asks an opening question such as, "What does this mean?" Students then express their opinions and respond to the opinions of peers, drawing ideas from evidence found in the documents. The ensuing discussion should work to provide greater clarity to the complexities of the topic. Finally, a debriefing session should take place to give context to the discussion. Debriefing may include a reflective writing or answering questions as a large group such as "What did we accomplish today?" Debriefing questions help students bring together various ideas and can be useful to encourage positive discussion norms for the future. Building understanding through seminar discussions can inform future projects that aim at solving problems, such as a structured academic controversy discussed below.

Structured Academic Controversy

In contrast to seminar discussions described above, a structured academic controversy works to uncover solutions to a problem. While Walter Parker's (2004) description of a structured academic controversy is commonly cited, David Johnson and Rodger Jonson (1985, 1988) developed the practice. Initially, a teacher or students should select a powerful issue and do research to gain a solid understanding beforehand. Background knowledge could come from independent research or through seminar discussions described above. Diane Hess (2009) advocated incorporating a controversial issue to encourage democratic problem solving. After selecting and researching issues to discuss, teachers should clearly articulate the purposes of the deliberation and encourage classroom norms of respect. Such norms emphasize that students listen to all sides equally, build on the ideas of others, back up opinions with clear reasons, and take turns speaking. Students start in small groups or pairs and are asked to research a specific stance on an issue. Next, students switch positions on the topic and advocate for the opposite side. Finally, students as a whole sort out their own position relative to the issue and brainstorm possible solutions. As a goal, students evaluate alternative courses of action related to a shared problem and ultimately address the question, "What should we do?" Following the group discussion, a large group debriefing can take place in order to bring together the ideas built in small groups. During this time, teachers encourage critiques in order to explore the complexities of the issue. Finally, follow-up writing assignments help students reflect on the issue.

Social studies practices are varied and may depend greatly on the school contexts, background of the students, and the expertise of the teacher.

The Future of Social Studies Education

Social studies education represents a complex and multifaceted field of study. While research and scholarship in the field will continue to investigate the learning of and teaching for social studies content, current trends occurring across the globe will also suggest new and relevant topics for social studies research. These topics may include the following:

- Determining the role of technology on the learning and teaching of social studies.
- Investigating the impact of globalization on social studies.
- Defining global citizenship and identity.
- Exploring immigrant education and teaching and learning social studies.
- Discovering ways to meet diverse learning and linguistic needs of students in social studies classrooms.
- Drawing distinctions and comparisons across varied international school contexts.
- Documenting the response to social studies education from individuals coming from marginalized communities.
- Tracing the influence of standardization on social studies teaching and learning.

Overall, the social studies field offers scholars ample opportunities to address important areas for research. As a field, social studies education is relatively young compared to other disciplines; therefore, traditions of inquiry are continually being formed and reformed.

Social Support and Recovery from Disease and Medical Procedures

Melika H Stephens and Keith J Petrie, University of Auckland, Auckland, New Zealand

Abstract

Social support has been shown to moderate the negative effects of chronic illness and speed recovery from medical procedures. The effect of social support, however, is dependent to a large degree on the fit between the type of support offered and the needs of the patient. A mismatch in the type or intensity of support can lead to difficulties and hamper recovery. Patients low in social support are more likely to present with advanced illness or die while in hospital. While the evidence linking social support and health outcomes is strong, the mechanisms that are operating are still largely unknown.

Social support is usually defined in terms of the individual feeling valued and cared for by their social network as well as how well the person is embedded into a network of communication and social obligation. A large range of studies has found social support to have an important relationship in recovery from illness and medical procedures. Researchers generally conceptualize and measure social support in three main ways. First, in terms of the individuals' perceptions that they have people in their social network that they can turn to in times of need. Second, in terms of structural aspects of the individual's social network which include the number of personal ties and network density. This includes the number of people the individual has a connection with, as well as their membership of formal and informal social groups or organizations. Third, social support is defined in terms of functional support or the aid and encouragement provided to the individual by the social network. This can be further categorized into the type of functional support provided, in terms of being instrumental, financial, informational, appraisal, or emotional. Research shows that these different types of social support have differential effects on recovery from illness (Cohen, 2004; House et al., 1988).

Social Support and Recovery from Disease

Evidence examining the effect of social support on recovery from illness comes from a variety of medical illnesses including cardiovascular diseases, cancer, infectious disease, and other illnesses. Under most circumstances, social support has been shown to moderate the negative effects of illness and improve recovery, while low social support has been associated with a poorer prognosis in many clinical conditions. The effect of social support, however, is dependent to a large degree on the illness and the match between the type of support offered and the needs of the patient.

Cardiovascular Disease

In the cardiovascular area, there is strong evidence that poor social support and social conflict are significantly associated with increased risk of cardiovascular-related morbidity and mortality (Everson-Rose and Lewis, 2005). Reviews of epidemiological literature show low social support to be a risk factor for the development of cardiovascular disease in healthy individuals (Eng et al., 2002; Lett et al., 2005). In patients with established cardiovascular disease, low social support is also associated with a poor prognosis. A study of elderly patients with myocardial infarction (MI) found those with low levels of emotional social support were more likely to die in hospital within 6 months of their heart attack, even after controlling for severity of MI and other risk factors (Berkman et al., 1992). A recent systematic review and meta-analysis found that in patients with Coronary Heart Disease (CHD), low functional support is consistently associated with cardiac mortality, even adjusting for other medical and demographic variables (Barth et al., 2010).

Williams et al. (1992) followed up 1965 patients with coronary artery disease after angioplasty. After accounting for known medical prognostic factors such as cigarette smoking and family history of heart disease, the most important socio-economic variable in predicting time to death was the presence or absence of a spouse or confidant. This finding is consistent with other studies of heart attack patients that have found a spouse to play a protective role in outcome. Patients with CHD who have small social networks have been found to have an increased mortality risk, and this elevated risk was not attributable to confounding by disease severity, demographics, or psychological distress (Brummett et al., 2001). Consistent with the work in CHD mortality and worsening CHD progression, a study on the progression of coronary atherosclerosis found social isolation to be an important risk factor for accelerated progression of the disease (Wang et al., 2005). There is also some evidence that social support is more protective for cardiovascular health among men compared to women (Orth-Gomér, 2009).

An interesting avenue of new research is looking beyond the single assessment of social support and health outcomes following an acute MI and to assess whether changing levels of social support during early recovery influence later health status. In a study using this approach, Leifheit-Limson et al. (2012) found patients with worsening levels of social support 1 month following their heart attack had more angina, greater levels of depression, and lower disease-related quality of life at 1 year, compared to those patients who had continued high social support. This research demonstrates that changing levels of social support may have important effects on patient

recovery from illness and there may be benefit from assessing social support at more than one time point.

Cancer

Another important area investigating the effect on social support on recovery from chronic illness is the effect of social factors in the progression and prognosis of cancer. This research demonstrates how different social support dimensions can differentially affect illness recovery, and how the relationship between social support and cancer progression can vary with different types of illness. A systematic review by Nausheen et al. (2009) found the evidence for the relationship between social support and cancer progression is strong for breast cancer but consistently unconvincing for other types of cancer. This review also found that structural support was found to be more frequently associated with disease progression for breast cancer than functional support.

In terms of cancer survival, a recent meta-analysis (Pinquart and Duberstein, 2010) showed that in controlled studies, having high levels of perceived social support, larger social networks, and being married were associated with decreases in relative mortality risk of 25, 20, and 12%, respectively. However, the relationship varied by cancer site, with stronger associations of social support in patients with leukemia and lymphomas and stronger associations of network size observed in breast cancer patients. Moderator analyses suggested that having never been married is associated with higher rates of mortality from cancer than those who have been divorced or separated. This research is also consistent with work by Ell et al. (1992) which showed that the relationship between social support and survival may operate differently depending on cancer site and extent of the disease.

Larger social networks have been associated with lower breast cancer mortality. A prospective study of 2835 women with breast cancer found that those individuals who were socially isolated before diagnosis were twice as likely to die of their breast cancer compared to socially integrated women (Kroenke et al., 2006). Pinquart and Duberstein (2010) noted that in their large meta-analysis of social networks and mortality among cancer patients, associations between social network and mortality were stronger in young patients.

Researchers are beginning to appreciate that the impact of large social network on breast cancer survival may depend on the quality and burden of these networks. A recent study found that larger social networks predicted better prognosis following diagnosis, however, this association depended on the level of social support and burden within relationships (Kroenke et al., 2013). Women with both small social networks and low levels of support had significantly higher risk of mortality than women with large networks and high levels of support. However, women with small networks and high levels of support did not have a significantly higher mortality risk compared to women with large social networks and high support. These results indicate that it is the quality of the social support, and not just the size of an individual's social network, that is important for survival following breast cancer.

Social attachment, a type of social support reflecting connections with others, has also been associated with a survival advantage for patients with ovarian cancer (Lutgendorf et al., 2012). Patients in this study were followed up from the date of their surgery until their death. The median survival time for patients with low social attachment was 3.35 years, compared to 4.70 years for those with high social attachment. Another important finding from this prospective study was the nonsignificant relationship between instrumental social support and survival. The relationship between social support and cancer mortality has also been found in Japan. Social isolation and the perception of low support from family members were associated with higher risk of colorectal cancer mortality in Japanese men (Ikeda et al., 2013).

Infectious and Other Diseases

A well-controlled study looked at the susceptibility to developing the common cold in volunteer subjects given nasal drops containing one or two cold viruses (Cohen et al., 1997). The results showed that those volunteers with more diverse social networks had a fourfold lower susceptibility to developing upper respiratory illness than those with a smaller number of social ties. In this study, social contact per se was not as important as the diversity of the individual's social relationships. The more an individual had regular contact with a variety of social groups such as family, workmates, neighbors, and other social networks, the more resistant he or she was to developing a cold.

Another study examining the role of psychosocial factors on progression to AIDS found stress and social support to be significant predictors of HIV disease advancement (Leserman et al., 1999). In a follow-up period of 5.5 years, those participants who were more satisfied with the level of social support offered by their friends and families at study entry were twice as likely to be free from AIDS than participants who were dissatisfied with their available level of social support.

As well as infectious diseases, social support has been shown to have a positive effect on prognosis and recovery in a range of other medical conditions and illnesses. A study of low-income pregnant women found social support was associated with fewer complications during pregnancy and a higher infant birth weight. Research has found women who receive higher-quality social support prior to delivery give birth to healthier babies and experience less postpartum depression. In chronic illnesses, Penninx et al. (1998) found positive effects on depression for having a partner and having many close relationships, although the strength of the effect differed across illnesses. Other work has shown social support to be associated with lower levels of disability and depression in patients with diabetes and higher levels of compliance in patients on renal dialysis.

Social Support Interventions

A large number of interventions have been trialed in health care to improve the level of social support to patients. These interventions vary in terms of whether a group or an individual format is used and whether the focus is on providing additional social support to patients or bolstering the effectiveness of their current networks. Interventions also vary according to the source of the social support in terms of whether support comes from a peer with the same or similar illness, a spouse or family

member, or a health professional (Hogan et al., 2002). The range of trials of interventions makes it hard to draw firm conclusions about the effectiveness of social support interventions. The most common reported effect is a reduction of psychological distress and an improvement in functional activity. However, the evidence is not clear about what type of social support intervention works best in a particular patient group.

A popular source of social support for patients with chronic illness is informal support groups. Here, patients meet together to discuss their condition and the difficulties and successes they have experienced in coping with their illness. As well as sharing personal illness experiences, these groups offer the advantage of providing information about utilizing health services, normalizing experiences and concerns, and providing emotional support to group members. An analysis of social support groups found that the experience of physical illness was the most common reason for participation in such groups (Lieberman and Snowden, 1993). Even after excluding substance abuse groups, this American survey found coping with physical illness made up 42% of the self-help group population. This study also suggested that these groups were more effectively accessed by the middle-class populations who often already have good access to other support services.

The limit of such social support groups for patients with physical illness was that participants had to be well enough to be physically able to attend meetings. However, the Internet has changed this requirement. In the last 5 years, there has been a dramatic increase in the use of the Internet in most Western households. This has been accompanied by an increasing number of discussion and support groups for chronic illness. Now, without leaving home, chronic illness sufferers can read postings from other sufferers and participate in discussions about aspects of their condition.

New types of online support web sites have also emerged in recent years. PatientsLikeMe.com is a web site where patients connect with others who have the same illness. The web site is set up for patients to track progress of their illness and share data on symptoms, treatment, side effects, and functioning. The web site now covers over a thousand health conditions and also acts as a forum for patients to share their experiences of their illness with others. PatientsLikeMe also aggregates data from other patients with the same illness so patients can compare how they are doing in relation to others. Aggregated data from PatientsLikeMe.com have also been used for peer-reviewed scientific papers (Wicks et al., 2010).

While patients are using web-based communities to connect with patients with similar illnesses, sometimes the recipient does not always see actions by others designed to assist with medical problems as helpful. Negative reactions to intended helpful actions of others are quite common. Patients often report receiving support that they did not want or not getting assistance for a daily activity when it was needed. This mismatch between the need and provision of support has been the focus of study in the general social support area and is very relevant to the area of recovery from medical illness (Thoits, 2011). Here, the evidence suggests that different types of support are differentially valued depending on the relationship the provider has with the patient.

In an important study with cancer patients, Dakof and Taylor (1990) found emotional support was most likely to be valued when it came from intimate others, whereas informational support was more valued when it came from a physician or another cancer patient. This study found when there was a mismatch, such as when a patient needed emotional support from a spouse but received advice or information, then these actions were more likely to be seen as unhelpful. Unhelpful behaviors noted by patients were minimizing the problem, forced cheerfulness, medical care delivered without any emotional support, and being told not to worry. A later study using patients with the chronic nonlife-threatening illnesses of irritable bowel syndrome and chronic headache found these patients to put greater value on tangible and practical assistance and less on emotional support than cancer patients (Martin et al., 1994).

These studies highlight how the characteristics of the illness may strongly influence the type of social support needed by patients. In some life-threatening conditions, where patients are frightened or daunted by the demand of treatment and prognosis, emotional needs are more prominent. In other illnesses, where the illness forms a major hurdle to be met on a more routine daily basis without the threat of disfigurement or death, then more practical issues such as assistance with childcare and transport become more valued.

A disparity in the intensity of social support can also cause difficulties for patients. Sometimes an aversion or fear of physical illness can cause family to avoid contact with the patient. While emotional support is the type of support most received by patients, it is also the type of support likely to be perceived as most inadequate. However, overly intrusive offers of assistance and help can also cause a negative reaction and increased stress. These findings highlight the importance of finding a balance between the needs of the patient and the type and level of social support.

Social Support and Recovery from Medical Procedures

Although not as extensively studied as recovery from illness, there is considerable evidence that social support also has a positive influence on recovery from hospitalization and medical procedures. Hospitalization is an anxious and difficult experience for most patients. Research shows social support helps to moderate the negative effect of hospitalization and to speed recovery from surgery.

Often surgical procedures involve postoperative pain and functional impairment, as well as psychological distress. Krohne and Slangen (2005) investigated the influence of patients' social support on subjective and objective stress indicators before, during, and after surgery. Patients who scored high on social support showed less anxiety, received lower doses of narcotics, and had a shorter hospital stay than did patients with low support. There is also evidence that social support influences mortality following surgery. In a prospective study of 1290 patients undergoing coronary bypass surgery, Herlitz et al. (1998) found that patients who agreed with the statement 'I feel lonely' prior to surgery had more than double

the risk of dying after the operation, compared with patients who did not feel lonely.

There is good evidence that social support also influences an individual's length of stay in hospital. Contrada et al. (2008) investigated social support in length of stay following heart surgery. Psychosocial interviews were conducted 5 days prior to surgery. Low social support demonstrated an independent, prospective association with greater length of stay, supporting the role of social support in influencing adaption to heart surgery. Visits from family or friends during hospitalization have also been associated with reduced hospital stay following coronary artery bypass surgery (Kulik and Mahler, 1989). Married male veterans who received high support, defined as more spousal visits, recovered more quickly and took less pain medication compared to those who received low support. Married patients who had high social support were released from hospital an average 1.26 days earlier compared to those patients who received low support.

A recent study examined social connectedness in veterans recovering from major thoracic or abdominal operations (Mitchinson et al., 2008). Social networks were assessed by the number of friends and relatives an individual had and how frequently contact was made with members of their social network. Patients reporting larger social network had lower pain and opiate use and anxiety than patients with small or nonexistent social networks. Smaller social network size was associated with the likelihood of staying in hospital for 7 days or more following these major operations.

One fascinating aspect in the study of social support and recovery from medical procedures is the effect of the patient's hospital roommate on recovery. Research in this area demonstrates that whether a patient has a pre- or postoperative roommate can influence outcome. Patients about to undergo surgery who are also assigned to a preoperative roommate show greater levels of anxiety and a slower recovery than those assigned a roommate who has already been through surgery. As well as lower levels of anxiety prior to surgery, being placed with a roommate who has been through surgery resulted in getting out of bed more quickly following the operation and a fast discharge from hospital (Kulik et al., 1993). It seems likely then that the positive benefits resulting from a postoperative roommate are partly due to the natural relief of seeing someone who has survived the same operation that the preoperative patient is about to undergo, and by normalizing the feeling and problems following the operation so these are less likely to be viewed as unusual or abnormal by the patient. Thus a roommate who has been through the operation or procedure can serve as a practical role model for preparing patients for the postoperative pain, physical sensations, and sequence of recovery following the operation.

This research was extended in a quasiexperimental study among patients undergoing cosmetic surgery (Kulik et al., 2000). Patients were assigned to rooms that either facilitated sufficient postoperative contact with other patients, or they were assigned to rooms that were physically located so that they had little interpatient contact. The results indicated that patients in the high patient contact condition experienced less postoperative anxiety and reported higher overall satisfaction with their quality of care compared to patients who received low contact. Analyses of patient-reported postoperative patient interactions suggest several additional benefits from this contact with fellow patients, including additional emotional support, a reduction in uncertainty about what to expect, and the chance to compare progress and emotional reactions. These results are consistent with the idea that another patient can serve a beneficial adjunctive role, positively influencing a fellow patient's postoperative emotional well-being and satisfaction with care (Kulik et al., 2000).

An individual's marital status has been shown to be related to patient outcomes following medical procedures. In a large study of 40 820 patients admitted to a University Hospital in Ohio, Gordon and Rosenthal (1995) found that unmarried patients presented to hospital later than married patients. Unmarried surgical patients also had a higher risk of dying in hospital than married surgical patients, even after controlling for severity of illness, diagnosis, and other demographic factors. Furthermore, unmarried patients tended to stay longer than married patients. The differences found in this study were greater in patients who had never married when compared with patients who were widowed, divorced, or separated. This study suggests that being unmarried and in particular, never having married, increases your risk of negative outcomes during hospitalization. Hospitalization can also have a negative effect on the health of those in a close relationship with the patient. In a study examining mortality after the hospitalization of a spouse, Christakis and Allison (2006) examined over 500 000 couples who were enrolled in Medicare in 1993 and looked at hospitalizations and death over a 9-year follow-up period. The researchers found that hospitalization of a spouse was associated with an increased risk of death among elderly participants. This risk varied between different diagnoses but was generally higher for men than women.

Recent research from the area of psychoneuroimmunology has shown that conflict in a close relationship can negatively impact wound healing. Kiecolt-Glaser et al. (2005) investigated how hostile martial behaviors modulate blister wound healing. Couples were assessed twice in a crossover analysis. During the first admission, couples engaged in a structured social support interaction. During the second admission, couples discussed a marital disagreement. Blister wounds healed more slowly following couples' conflict discussions than after more supportive interchanges, and couples who were more hostile toward each other during both discussions had wounds that healed more slowly than couples whose interactions were less hostile. The overall differences related to hostility were substantial; small blister wounds in high-hostile couples healed at only 60% of the rate of low-hostile couples. Thus, wound healing appeared to be responsive to both the short-term stress of a conflict, as well as hostile behavior. Thus, while marriage may have beneficial effects of recovery, inadequate support or conflict could cancel out this effect.

Summary

The available evidence suggests social support has a positive influence on individuals' susceptibility to infectious disease and recovery and adjustment to a variety of chronic illnesses. In the cardiac area, there seem to be particularly strong benefits for

having a spouse or close confidant and these effects seem to be even stronger for men. With the rise of the Internet, electronic social support groups are providing an important source of information and peer support for patients with chronic illness. There is strong evidence that the lack of social support is a risk factor for negative outcomes following hospitalization. Patients low in social support are more likely to present with more advanced illness and to be more likely to die while in hospital. However, it should be noted that many of the studies in the area are correlational, and the mechanisms that link social support to recovery from illness are still largely unknown. Recovery from surgery is an example where action by others that conveys to patients that they are respected and valued has a positive effect on outcome. The type of roommate can also set up a more positive outcome from the operation by providing a constructive role model by minimizing catastrophizing and demonstrating effective coping strategies. A critical factor running through social support and the recovery from illness and medical procedures is the match between the needs of the patient and the type of social support provided. Different types of illness and procedures cause differing needs in terms of whether they require more emotional or tangible support. Emotional support is valued highest when it comes from a significant other. A mismatch in the type or intensity of support can lead to difficulties and hamper overall recovery.

Abstract

This article examines the treatment of the social system in the sociological and related literature. The social system is the main concept of sociological systems theory, which conceptualizes societies as well as groups within them as systems, spanning from classical to contemporary sociology and related to general systems theory in the physical and related sciences. The article addresses such issues as the defining properties of the social system, types of social systems, classifications of historical–empirical social systems, and structural elements of the social system.

The concept of 'social system' is one of the key concepts of sociology, especially its theoretical strand (Barber, 1993; Fararo, 1989; Luhmann, 1995; Parsons, 1951; Sorokin, 1957), and is used to describe and analyze society as well as various social groups within it. (Fararo (1989: p. 64) remarks that "thinking in terms of systems is an important element of theoretical sociology.") In this approach, society is conceptualized and analyzed as a general or total 'social system' and social groups as particular 'social systems' or subsystems that compose it. In particular, 'social system' forms the principal concept of sociological systems theory originating in early sociology (Collins, 1988; Fararo, 2001; Habermas, 2001), as well as applying and extending (Luhmann, 1995) general systems theory from natural science (Bailey, 1994; Berrien, 1968; Bertalanffy, 1975; Buckley, 1967) into the social and behavioral sciences.

Defining Properties of the Social System

The concept of social system is in the sociological and related literature defined by a number of essential properties that are typically interrelated and mutually reinforcing. First, the social system is defined by constitutive, structural properties (Giddens, 1984), thus as a set of constituents, i.e., parts, units, components, or structures. By virtue of these properties, the social system represents and operates as a structured and differentiated complex (Fararo, 1989; Luhmann, 1995) of elements of a social character. Among early sociologists, Comte (1983[1830–52]) states that every social or other system is composed of elements of the 'same nature with itself,' Pareto (1963[1916]) treats society and group as a 'social or an economic system' and its elements as constituting such a system, Simmel (1964[1908]) identifies system 'structure,' Weber (1968[1920]) refers to society as the 'general structures of human groups,' and Parsons (1951) regards the social system as having a 'structure.' Contemporary sociologists also characterize social systems as having 'structures or structural properties,' although not being structures in themselves (Giddens, 1979).

Second, the social system is defined by emergent properties, thus as an emergent phenomenon resulting from and typified with the combination, interrelations, interaction, association, and cooperation of elements. In terms of its emergent properties, the social system is considered the system of action and interaction between individual and especially collective actors. In early sociology, both Marx (1933[1849]) and Durkheim (1982[1895]) define the social system, i.e., society as more than an aggregate or sum of individuals and in terms of their 'relations' or 'association,' although the first emphasizes the 'relations of production in their totality' as constituting the 'social relations, society,' and the second focuses mostly on their noneconomic, nonmaterial forms like social institutions, while Spencer (1969[1876–96]) suggests that a necessary condition for the formation of society in the 'sociological sense' represents cooperation (spontaneous or consciously devised), beyond mere 'juxtaposition.' (Habermas (1975: p. 2) comments that "Marx developed for the first time a social-scientific concept of system" as well as system crisis in the form of capitalism. In turn, according to Collins (1988), "Spencer [was] the first general systems theorist.") In particular, Durkheim (1965a[1893]) proposes that the social system created by the 'association,' i.e., 'positive and durable relations' of a 'plurality of individuals' constitutes a 'specific reality' with its own distinct irreducible properties, thus an emergent phenomenon from their 'uniting together,' which forms the 'base' on which all social life is built. Similarly, Tönnies (1955 [1887]) characterizes society as a social system involving reciprocal relations or interactions, Pareto (1963[1916]) proposes that socially connoted elements compose the social system only through 'mutual correlations in social phenomena,' and Simmel (1964[1908]) considers 'large (social) systems' to be 'immediate (and constant) interactions' among individuals crystallizing as 'autonomous phenomena' and attaining their 'own existence and laws,' indicating emergent system properties. (However, Simmel (1964[1908]) relaxes, if not contradicts, the characterization of social systems by emergent properties stating that society "merely is the name for a number of individuals, connected by interaction", as also Smelser (1997: p. 30) comments.)

In later sociology, Sorokin (1957) defines social systems as 'systems of social relationships,' 'systems of interaction,' and the 'network of social relationships,' and Parsons (1951) as 'systems of social action' involving units and their 'structural interrelations,' a 'system of processes of interaction between actors,' thus the 'structure of the relations' between actors and

a 'network of interactive relationships.' In a similar vein, contemporary sociology characterizes social systems as 'systems of social interaction' with 'structures or structural properties' (Giddens, 1979) and 'social action systems' (Fararo, 2001).

Third, the social system is defined in the sociological and related literature by causal properties such as reciprocal causation or conditioning, codetermination, and interdependence. On account of such properties, the social system constitutes a causal, interdependent complex of interrelated elements generating various systemic outcomes during its own operation and in interplay with the environment (Luhmann, 1995). Spencer (1969[1876–96]) states that the units of the social system tend to be in the 'state of mutual dependence,' Durkheim (1982[1895]) posits that social systems are linked by 'bonds of interdependence,' Simmel (1964[1908]) asserts that society always involves connected individuals by 'mutual influence and determination,' and Mannheim (1956) proposes that a social system is characterized with 'causal sequences' operating recursively in its social structure. Also, contemporary sociologists conceive social systems as consisting of 'regularized relations' of interdependence between individuals or groups, i.e., social practices (Giddens, 1979), and as 'relations among elements' that are regulated through reciprocal 'conditioning' with 'successful conditionings' acting as systemic constraints (Luhmann, 1995).

Fourth, the social system is defined by unifying properties, and thus in terms of unity, unification, and integration. With regard to such properties, the social system represents or reaches a unity or union of interrelated and interdependent elements. Durkheim (1965b[1915]) argues that social systems have a 'certain unity'; Simmel (1955[1923]) assumes that they tend to reach their 'unity' in the form of their 'organic structure.' Contemporary sociological systems theorists condense these properties characterizing social systems in the terms of the 'unity of the whole' (a *unitas multiplex*) (Luhmann, 1995).

Fifth, the social system is defined by institutional, organizational, and functional properties, i.e., in terms of institutions and rules, organizations, and functions. In this respect, the social system constitutes an institutional, organizational, and functional complex or arrangement of interrelated, interdependent, and unified elements, i.e., a set of institutions and rules, organizations, and functions. Tönnies (1955[1887]) describes the modern social system (*Gesellschaft*) as an 'entirely artificial, man-made institution' permeated with a 'system of conventional rules,' Sorokin (1957) incorporates 'associations, organizations, institutions, and their interdependence' as well as entire societies or cultures into social systems, Parsons (1937) contends that the 'structure' of social systems entails especially 'institutionalized patterns' as well as 'a commonly understood system of cultural symbols,' and Merton (1968) registers the 'interdependence between social institutions' constituting a social system. Contemporary sociologists note that modern social systems theory concentrates on the 'functional rationality of large organizations' in Weber's tradition (Habermas, 2001), and that functionalism is a major 'subtype of system theory' (Collins, 1988). (Collins (1988: p. 80) adds that "classical Marxian theory is above all a system theory. It sets out all the elements of a social system and shows how they interrelate. The model is both static and dynamic.")

Sixth, the social system is defined by collective, objective, and complex properties. In this sense, the social system constitutes a supraindividual entity or collectivity of interrelated, interdependent, unified, and institutional elements characterized with objectivity and complexity. Durkheim (1966[1897]) postulates that the social system, above all society, represents inherently a 'system' of collective objective realities in being composed of other simpler societies or groups (the simplest being horde or clan), and similarly, Parsons (1951) considers both a society as a total social system and any 'complex partial social system' to be a 'network of collectivities.' Simmel (1955[1923]) recognizes that social systems are 'superindividual' entities, notably society being a 'structure' transcending individuals and the 'universal' but 'concretely alive,' such that the 'objective structure' of society forms a 'framework' of individuals and their characteristics and activities. Evoking Durkheim and Marx, contemporary sociologists depict social systems like societies as 'systems of objective relations' or 'objective potentialities' in the present reality, in particular, the 'material conditions of existence of a class condition' (Bourdieu, 1988), and suggest that the social system is an objective and external 'environment' for individual agency, thus causing structures to exist 'outside of actors' only within this systemic context (Alexander, 1998).

Seventh, the social system is defined by static, reproducing properties such as persistence or gradual change, self-reproduction, self-coordination, self-regulation, and self-evaluation or self-reflection. On this account, the social system constitutes a static, persistent or gradually changeable, self-reproducing, self-coordinating, and self-reflective or self-referential complex of interrelated, interdependent, unified, institutional, collective, and complex elements. Parsons (1951) defines a social system as a 'mode of organization of action elements' in connection with the 'persistence or ordered processes of change' of the system's 'interactive patterns.' Similarly, contemporary theorists stipulate that the particular elements constituting the social system have 'no duration' relative to it as a relatively enduring entity constantly reproducing them and thus expressing a 'peculiar constraint on autonomy' to the effect that the necessary condition for system existence is its endowing its 'momentary elements' with the 'capacity for connection' and thus their reproduction (Luhmann, 1995). In this context, social systems constitutes and function as systems only if referring to 'themselves' (Luhmann, 1995), thus becoming 'self-referential' (Collins, 1988).

Eighth, the social system is alternatively defined by non-static, dynamic properties such as growth, development, substantial or rapid transformation, and change, including crisis. In this regard, the social system constitutes an actually or potential dynamic, including crisis-prone, complex of interrelated, interdependent, unified, institutional, collective, complex, and reproducing elements. In early sociology, Comte (1983), Spencer (1969[1876–96]), Marx (1967[1867]), Tönnies (1955[1887]), Durkheim (1966[1897]), Simmel (1990[1900]), Pareto (1963[1916]), and Weber (1968 [1920]) observe, emphasize, and predict rapid and substantial social system change or dynamics, including crisis, especially recurring economic as well as political, religious, and moral crises in modern society. Also, some contemporary sociologists point to a 'system crisis,' particularly economic and

political crises, in the modern social system such as capitalist society (Habermas, 1975), and generally to the existence or possibility of 'dynamical social systems' (Fararo, 1989).

Ninth, the social system is defined in the sociological literature by time and space properties or coordinates. Owing to such properties, the social system exists and develops as an entity situated and delineated in time and space incorporating interrelated, interdependent, unified, institutional, collective, complex, reproducing, and dynamic elements. In such a characterization, by contrast to structures social systems exist, persist, and change in time–space, while being composed of concrete 'social practices' (Giddens, 1979, 1984).

Lastly, the social system is defined by bounded properties, i.e., boundaries or limits of their operation and validity, and thus degrees of relative closure and openness. Consequently, the social system constitutes a bounded or boundary-maintaining and relatively closed or open set of interrelated, interdependent, unified, institutional, collective, complex, reproducing, dynamic, and time–space elements. Parsons (1951) treats the social system as an instance of 'boundary-maintaining' systems, while critics observe that 'one of the prevalent (and 'unfortunate') 'connotations' of the term 'system' is its 'closedness' (Dahrendorf, 1968) and thus boundary maintenance. In this definition, they are boundary-maintaining systems by creating and maintaining 'boundaries' as a distinguishing trait of 'system' vs. 'structure' (Luhmann, 1995), although only modern societies such as nation-states are observed to have 'specifiable boundaries' (Giddens, 1984). (According to Giddens (1984: p. xxvi) the "degree of systemness in social systems is very variable and societies rarely have easily specifiable boundaries [until] the modern world of nation-states.")

Types of Social System

Certain (ideal or pure) types of social systems are distinguished in the sociological and related literature. In one typology, social systems are classified into simple and complex types, with intermediate cases, on the basis of the degree of simplicity or complexity of their structure or organization and functioning. Durkheim (1965b[1915]) seeks to identify a 'social system surpassing all others in simplicity' and contrasts it to more complex systems arising from various combinations and extensions of the simple, primitive type. In contemporary systems theory, what typifies complex social and other systems is the necessity of adaptation both to their 'environments,' i.e., other systems, and their own 'complexity' (Luhmann, 1995), with modern 'liberal society' being regarded as 'much more complex system' than portrayed by rational choice theory as the economic model of both market and noneconomic systems (Munch, 1994).

Another typology incorporates total and partial social systems. This is the probably most important typology in sociological terms as it distinguishes society as a total social system from its units such groups or collectivities ('societies') and domains within it as such partial systems. Durkheim (1965a[1893]) uses the term the 'total' social system with reference to society as a whole as distinguished from 'partial' systems or societies within it, including 'domestic society,' 'economic society,' 'religious society,' etc., and also Pareto (1963[1916]) understands the 'sociological system' in the meaning of societal totality. In particular, Tönnies (1955 [1887]) observes that modern capitalist 'Society' epitomizes a total social 'system' in the sense of being a 'totality' in respect of the 'limitless' scope of application of a 'system of conventional rules.' This elaborates on or evokes classical Marxian sociological theory in which the total social system analyzed is modern capitalism (Collins, 1988).

Elaborating on Durkheim and Pareto, Parsons (1951) explicitly distinguishes total and partial social systems as societal and subsocietal systems, respectively. In this typology, a total or 'empirically self-subsistent' social system, in the sense of fulfilling 'all the essential functional prerequisites of long-term persistence from its own resources,' represents a society, while any other social systems being 'partial.' Notably, Parsons (1951) proposes that society is a 'norm' for the social system such that any 'partial' social systems are placed and analyzed in its 'setting' as its parts. Sorokin (1957) defines a social system as 'unlimited, or totalitarian' in its 'extensity' to the extent of its embracing 'all the relationships of its members,' regulating their 'entire behavior and all their interrelations,' while distinguishing 'totalitarianism' from *laissez-faire* as the 'fluctuation of the quantitative aspect of the network of social relationships.' Sorokin's dichotomy of totalitarianism and *laissez-faire* is not identical to Durkheim-Pareto-Parsons' typology of total and partial social systems, so long as total social systems cum societies are not necessarily 'totalitarian,' while partial systems not invariably being *laissez-faire*. A contemporary distinction between the 'double meaning' of society as a 'bounded system' and as 'social association in general' (Giddens, 1984) implies a distinction between total and partial social systems cum societies and groups, respectively. Thus, modern national societies are considered the sole or main example of a 'bounded' social system. Also, a dichotomy between continuous and discontinuous social systems is implied in Simmel (1964 [1908]) observing that under certain conditions 'society would break up into a multitude of discontinuous systems.'

The probably most common typology incorporates closed and open social and other systems is based on the relative degree of system closure and openness and of rigidity and fluidity of boundaries. Generally, a closed social system attains (monopolistic) closure and maintains its rigid boundaries in relation to other systems as the environment (Parsons, 1951; also, Collins, 1988; Habermas, 2001; Luhmann, 1995), in contrast to an open system characterized with openness and fluid or permeable boundaries. Weber (1968[1920]) defines a social system or relationship as closed against 'outsiders' to the extent that their participation in it is 'excluded, limited, or subjected to conditions,' and open so long as the 'system of order' permits such participation to 'anyone' outside of it. In his view, a social system is closed or open depending on traditional, affective, and instrumental- and value-rational determinants, and the 'principal motives' for system closure involve "(a) the maintenance of quality; (b) the contraction of advantages in relation to consumption needs; (c) the growing scarcity of opportunities for acquisition" (Weber, 1968[1920]). An exemplar of this dichotomy is that between 'status society' and 'class society' (Weber, 1968[1920]) as closed and open social/stratification systems, which also

depicts or predicts a trajectory and development from system closure to greater openness – and to some extent renewed closure followed by a new opening, and so on – as do most classifications based on this criterion (Habermas, 2001; Luhmann, 1995). For example, Mannheim (1956) identifies 'different social systems of authoritarian and democratic character' in which the first embody closed 'order' and 'discipline,' and the second 'fluidity' and 'openness' as 'antithetical human ideals,' and which also represent successive, lower, and higher phases of system evolution in modern society.

Much of contemporary sociological and general systems theory treats closed social and other systems as a 'limit case' in the sense of systems attributing 'no significance' to the environment in contrast to open systems typified with such an attribution (Luhmann, 1995). Furthermore, some versions replace the closed–open system dichotomy with the distinction between 'self-referential closure' and 'openness' yielding the concept of self-referential, self-producing (autopoietic) social and other systems (Luhmann, 1995), which consider their own interrelations and goals 'part of the environment' (Collins, 1988). This is done on the ground that the dichotomy does not represent an 'opposition of types but a relationship of intensification' in that social and other systems may close and open at the 'same time' through intensifying and relaxing their boundaries as 'specific mechanisms' for the 'purpose of separating yet connecting (via) selection,' so the notion of a self-referential closed social system is not inconsistent with its 'openness to the environment' (Luhmann, 1995; also, Habermas, 2001).

Classification of Historical and Empirical Social Systems

Various classifications of historical–empirical social systems, first and foremost taxonomies of past and present societies, in the sociological and related literature (Lenski, 1994) can be divided into evolutionary and cyclical. Evolutionary (linear and nonlinear) and cognate classifications are prevalent in the literature, and treat social systems at certain historical–empirical stages as irreversible or nonrecursive over time in a continuous sequence from the lowest to the highest types as the supposed beginning and pinnacle of societal evolution.

In early sociology, Comte (1983) classifies historical social systems and the 'general systems of conceptions,' based on prevalent 'principal conceptions,' into the theological system, including the 'theocratic' and 'military' polity exemplified by feudalism, the metaphysical, and the positive, i.e., rationalistic, scientific, and industrial, as the assumed 'final' state of evolution. Spencer (1969[1876–96]) essentially adopts Comte's classification by classifying social systems, on the basis of 'unlikeness' between the kinds of predominant social activity and the 'resulting unlikeness' of organization, into 'militant' and 'industrial' types, the first being premised on the 'system of status' involving 'successive grades of subordination' and the principle of 'compulsory cooperation,' the second (in its 'ideal form') on the 'system of contract' and 'voluntary cooperation.' Spencer's (1969[1876–96]) full classification of historical social systems, in accordance with their 'degree of composition,' incorporates 'simple, compound, double-compound, trebly compound, and predominantly militant and predominantly industrial' societies. Marx (1933[1849]) classifies historical social systems into tribal, Asiatic, Ancient, feudal, and modern capitalist (or bourgeois) societies deemed 'totalities of relations of production' and different 'modes of production' as 'epochs' manifesting 'progress in the economic development of society' to be fully realized in a future postcapitalist society (communism). Similar to Comte and Spencer, his historical taxonomy of social systems assumes the main form of a dichotomy between 'feudal society' and the 'capitalist regime,' and thus an evolutionary transition from the first to the second system in treating the 'economic structure of capitalist society' (the 'bourgeois order') as emerging from 'the economic structure' of feudalism (Marx, 1967[1867]).

The probably best known and also most debatable sociological dichotomy of historical–empirical social systems is that of Tönnies (1955[1887]) dividing them into traditional Community (*Gemeinschaft*) as the 'lasting and genuine form of living' involving 'all intimate, private, and exclusive living together,' and modern capitalist Society (*Gesellschaft*) as instead 'transitory and superficial' typified by 'public life,' in a developmental sequence from the first to the second. However, Tönnies (1955[1887]) does not consider capitalist Society the final point of societal evolution or a desirable social system mostly on the account that 'all noncapitalists' within it are treated either 'like inanimate tools' forming the 'very essence of slavery' or as 'legally nonentities' denied the capacity for 'rational choice' consistent with Marx and contrary to Comte and especially Spencer. Specifically, Tönnies (1955[1887]) proposes that the 'whole movement' of historical–empirical social systems involves a 'transition' from 'original, simple, family-based communism' (Community) through 'absolutely detached' capitalism (Society) and ultimately to 'state-based and international socialism' resulting from the capitalist system.

Similar but identical to Tönnies, Durkheim (1965a[1893]) classifies total social systems into a society constituting a 'totality of beliefs and sentiments common to all members' ('collective conscience') and a 'system of different, special functions that definite relations unite,' i.e., societies with mechanical and with organic solidarity in an assumed evolutionary trajectory from the first to the second. Durkheim (1965a[1893]) states that an 'historical law' of societal evolution is that initially exclusive 'mechanical solidarity' tends to 'progressively' weaken, and 'organic solidarity' resulting from the highly developed division of labor to eventually prevail, thus 'two social types' corresponding to these 'two types of solidarity' indicated by repressive and restitutive law, respectively.

Simmel (1955[1923], 1990[1900]) provides various historical instances of social/stratification systems such as the Hindu caste system (also, Sorokin, 1957), the estate system in Europe, the class system, the merchantilist system, the ancient regime, the despotic regime, and the modern 'money economy' and culture as the latest and growingly important or prevalent example. Weber (1968[1920]) condenses various historical social-economic systems into traditional and modern

rationalist society/state/culture, notably economic traditionalism and rationalism epitomized by feudalism and modern capitalism, respectively, in an assumed (nonlinear) evolutionary trajectory from the first to the second (Parsons, 1937). (Parsons (1937: p. xv) describes Weber as "overwhelmingly the most important of the post-linear evolutionists.") Mannheim (1936) accepts Weber's dichotomy by distinguishing traditionalism and modernism in a developmental process from the first to the second, as does Parsons (1966) in his classification of concrete social systems into 'primitive, intermediate, and modern' societies, with the latter, specifically America, extolled as the last point and pinnacle of societal evolution (also, Giddens, 1984).

Cyclical and pseudocyclical classifications are also found in the sociological and related literature, and consider historical social systems recursive or recurring and reversible over time, as specific predictable elements or stages of an overall system cycle or rhythm alternating or fluctuating between them with some degree of regularity and so predictability, even if not necessarily periodicity (e.g., 10 or so years as in economic cycles prior to the Great Depression). Tönnies (1955[1887]) implies a cyclical system classification or conception registering 'a continuous process of simultaneous progress and decline' of some sociocultural systems (e.g., Germanic culture since the Roman Empire), and also observing that 'the power of Community, even in decline,' persists in the 'era of Society' qua capitalism and as the 'true reality of social life.' Moreover, the cyclical element is more explicit in Tönnies' (1955[1887]) observation and prediction that Community is or will be revived in modern 'socialism' after its decline in 'capitalism,' compatible with Marx's developmental trajectory from primitive to future 'communism' via the 'capitalist system' and other class-based social systems (Giddens, 1984) as an intermediate stage.

Among these classifications, the probably most explicit and prominent or notorious is Pareto's (1963[1916]) cyclical classification of past and present sociopolitical systems into aristocracy as elite rule, transient democracy as the '(un)stable reign by the masses,' and again aristocracy or oligarchy, and so on in the process of constant cycle or 'circulation of elites' versus the 'people.' Pareto (2000[1901]) contends that such cycles in societal rule recur in accordance with the 'great law of rhythm' in society, including 'waves' in ethics, religion, and politics, just as in economy (the 'business cycle'). Also, Sorokin (1957) presents a modified cyclical classification of historical social-cultural systems into 'ideational, sensate, idealistic, and mixed,' specifically systems of 'ascetic ideational,' 'active ideational,' 'active sensate,' 'passive sensate,' 'idealistic/mixed,' and 'cynical and pseudoideational' mentalities. Like Pareto, Sorokin (1957) posits what he denotes a 'rhythm of rise and decline of Ideational-Idealistic-Sensate' sociocultural systems, and even a 'super-rhythm' of such 'supersystems' of society/culture.

Structural Elements and Relations of the Social System

The structural elements of social system are denoted structures or subsystems, ranging from economic and political to cultural and others, and considered interconnected and interdependent.

Various divisions and conceptions of social-system structural elements or subsystems are found in classical and contemporary sociology and the related social sciences. In classical sociology, Comte (1983) incorporates in the social system such elements or subsystems as the 'social economy,' the polity, 'intellectual' and 'moral' phenomena, i.e., material, political, intellectual, and moral 'order' and 'power.' Marx (1970[1859]) distinguishes the 'economic structure of society' as the latter's 'real foundation' from its 'legal and political superstructure' and 'forms of social consciousness.' Spencer (1969[1876–96]) divides social-system elements into 'coordinating structures and functions' such as family, political and ecclesiastical structures and functions, and ceremonial institutions, and structures and functions 'coordinated' like 'regulative and operative industrial structures.' In his view, such structures and functions constitute the 'organization and life of each society' characterized with the 'interdependence of structures, functions, and products.' Also, Durkheim (1982[1895]) considers religious, moral, political, legal, and economic institutions – defined generally as 'all the beliefs and the modes of conduct instituted by the collectivity' – to be structural elements of the social system, including 'present-day social institutions.' For classical sociologists, especially Comte and Durkheim, the social system is logically and empirically both more comprehensive in scope and more complex in structures and functions than any of its structural elements or particular systems, including economy (except for Marx), as well as polity. Pareto (1963[1916]) condenses and articulates this position stating that the general 'sociological system' in the sense of society is invariably 'much more complicated' than the economic and any particular system.

Within later sociology, Sorokin (1957) and Parsons (1967) treat and denote social-system elements as 'subsystems' or 'structural components.' Parsons (1951) classifies the 'structural components of the social system' into the act as the unit of any 'system of action,' the status role as a 'higher order unit' in a 'macroscopic analysis of social systems' due to statuses and roles being 'not attributes' of actors, but the 'units of the social system,' the individual actor as a 'composite bundle' of statuses and roles vs. personality as a 'system of action,' and collectivity as 'actor and as object.' In particular, Merton (1968) focuses on the 'concept of social status' as a structural component or 'position in a social system' involving a 'distinctive array of designated rights and obligations,' and on the 'related concept of social role' referring to the 'behavior of status-occupants' in view of the 'patterned expectations of others.' In turn, Dahrendorf (1959) centers on the 'capitalist class system,' contrasted with the precapitalist chieftain system, in connection with the stratification 'system of social rewards,' as the crucial structural component of the modern industrial social system.

Similarly, contemporary sociologists emphasize 'stratification systems' (Collins, 1975) and different societal, including economic, political, and cultural-symbolic, 'domains' or 'fields,' 'power' or 'capital,' and 'subsystems' (Bourdieu, 1988) as 'social system parts' (Alexander, 1983)

or 'units' (Luhmann, 1995). For example, some divide 'constituents of social systems' into the 'exchange between social systems and their environment,' the 'goal values of social systems,' and the 'level of development of society' (Habermas, 1975), in which, however, 'social subsystems' by operating per their own logics or languages tend to be 'deaf' to their 'external effects,' as exemplified by the markets with its logic/language of prices (Habermas, 2001). According to another contemporary systems theory, social and other systems involve subsystems in the sense of 'internal system/environment relations within the system' and are disaggregated into 'elements and relations,' resulting in growing 'system differentiation' and 'system complexity' (Luhmann, 1995).

The structural elements or subsystems of a social system are typically characterized with interconnection and interdependence. Comte (1983) emphasizes the 'action and reaction of the different parts of the social system,' Marx and Engles (1947 [1847]) the 'connection of the social and political structure with production' forming the economic structure, and Simmel (1990[1900]) the interaction between an 'ideal structure' and an 'economic structure.' Sorokin (1957) and Parsons (1951) stress the interaction or interchange between various, including cultural, economic, political, and communal, subsystems in the total social system, and Merton (1968) the 'interdependence between social institutions' within the latter. In particular, Dahrendorf (1968) suggests that the 'social structure of power and authority' is linked with, by virtue of preceding and explaining, social stratification as a 'system of distributive status, i.e., a system of differential distribution of desired and scarce things,' as two structural components of the social system.

The Economic System and the Social System

One structural element or subsystem of the social system consists of the economy, i.e., the economic system. Sociological systems theory identifies and focuses on certain features, components, and effects of the economic system analyzed within the framework and operation of the total social system in contrast to conventional economics mostly analyzing economy as an isolated, independent, self-contained entity in relation to society.

First, these features of the economic system include cooperation and the division of labor. Comte (1983) states that 'in society the elementary economy' is characterized with the sentiment and activity of cooperation as 'preponderant' (and with 'sympathetic instinct' as secondary), thus the 'principle of cooperation' providing the basis for 'social statics' applied to economy, which anticipates 'comparative statics' in economics (Samuelson, 1983[1948]) and its extension in social systems theory (Fararo, 1989). Similarly, Spencer (1969[1876–96]) characterizes industrial society by the principle of voluntary and spontaneous cooperation implemented and expressed through the 'system' of commercial and other contracts. In particular, Comte (1983) sees the social division of labor, i.e., the 'distribution of functions' as the crucial feature of the modern economy, as do Spencer (1969[1876–96]) and especially Durkheim (1965a[1893]) who emphasizes the societal causes and effects of this process, as well as Marx (1967[1867]) analyzing its adverse results, and Adam Smith (1976[1776]) in economics focusing mostly on its internal operation and productivity within a production unit.

Sociological systems theory identifies another cardinal feature of the economic system in the production, distribution, and consumption of wealth or material goods as the standard definition of the economy and thus the subject matter of economics, especially its classical variant represented by Smith and his successors (Ricardo, Say, Mill, Marx as an economist, etc.). A variation on this feature is Marx's concepts of the forces and relations of production, the first comprising productive instruments combined with labor, and the second property relations in the sense of exclusive ownership and control of these resources in relation to nonowners. Marx (1970[1859]) uses the 'totality of these relations of production' to define and conceptualize the 'economic structure of society' considered the 'real foundation' for erecting a 'legal and political superstructure' and reflected in 'definite forms of social consciousness.' Durkheim (1982[1895]) notes that wealth is the 'object of political economy' as a social science in virtue of being deemed a defining and constitutive feature of the economic system, although rejecting economics' focus on the 'desire for wealth' as the supposed sole or main human motive. Durkheim (1994[1909]) includes among economic institutions those 'institutions relating to the production of wealth (serfdom, tenant farming, corporate organization, production in factories, in mills, at home)' and 'institutions relating to (its) distribution (rent, interest, and salaries).' Parsons and his associates consider wealth the main feature and outcome or output of the economic system for the 'total society' (Parsons and Smelser, 1956), and later sociologists suggest that economy solves the 'problem of production of economic resources or wealth for the social system' (Fararo, 2001), and note 'national systems of production' of wealth among modern societies (Habermas, 2001).

In sociological systems and other theories, like economics, additional and related attributes and elements of the economic system comprise exchange, money, prices, markets, contracts, entrepreneurship, and the like. Spencer (1969[1876–96]) defines 'industrial society' by the 'system of contract' in the economic and entire social system as a legal form of voluntary and spontaneous cooperation. Tönnies (1955[1887]) considers the 'market system' the essence and even equivalent of modern capitalist Society, and particularly emphasizes that, above all, within such a 'social system' money operates as 'power over all goods and pleasures' reducible to it as a 'common denominator' evoking Marx's (1967[1867]) theory of money. Also, Simmel (1990[1900]) considers and denotes the modern and in part earlier economic system as the 'money economy.' Weber (1968[1920]) depicts the market/price system as a 'struggle of man against man,' with money as its primary 'weapon' and prices as its 'expressions,' including a 'monetary system with the highest degree of formal rationality' in the form of financial accounting, as does in a similar way Veblen (1898). Weber (1968[1920]) implies that a defining feature and integral element of the modern capitalist economy is an 'economic establishment' constituted and operating as an 'organized system of continuous economic action,' thus what Mannheim (1956) calls the 'entrepreneurial system,' as Schumpeter (1949[1911]) especially analyzes and

emphasizes in economics. In turn, Durkheim (1994) exemplifies economic institutions and systems also by those institutions 'relating to exchange,' including 'commercial organization, markets, stock exchanges,' and as well as by 'monetary or financial systems,' and observes that contracts pervade economy while 'merely' expressing the 'respective state of economic forces.'

Also, sociological systems and related theory distinguishes various types of economic systems, as a particular variation of its typology of the total social system. Comte (1983), like Saint-Simon (1964[1816]) before, and Spencer (1969[1876–96]) identify and contrast primitive and modern economic systems, in particular feudalism and serfdom versus industrialism and capitalism. Marx (1933[1849]) identifies, within his central focus on capitalism, precapitalist, capitalist, and post-capitalist, including socialist and communist, economic systems as successive stages of the evolution of the economy, while predicting the 'inevitable destruction of the middle bourgeois classes and peasant estate under the present (economic) system' as the 'system of bourgeois economy.' As a variation on Marx's typology, Tönnies (1955[1887]) differentiates communal, capitalist-market, and socialist economic systems in an evolutionary sequence from the first through the second and to the third. Similarly, Simmel (1990[1900]) sharply contrasts the natural or self-subsistent economy versus the money economy, and Weber (1968[1920]) economic traditionalism and capitalism as exemplary economic modernism or rationalism.

Furthermore, sociological systems and related theory analyzes the relations between the economic system and the social system, unlike orthodox economics due to its treatment of the economy as an isolated, self-contained entity. Notably, it defines and specifies these as the relationship between economy as an element or subsystem and society as a system, i.e., as a part and a whole, in contrast to and differentiation from orthodox economics treating the first as the overarching system virtually outside and beyond society. Moreover, the relationship between the economic and social system, i.e., economy and society, has been a prevalent and continuing concern of sociological theory since Comte and Marx through Durkheim, Weber and Pareto through later (Parsons, 1937; Parsons and Smelser, 1956) and contemporary systems and other theorists (Fararo, 2001). (Fararo (2001: p. 177) suggests that "much of the tradition of general theoretical sociology has concerned the relationship between economy and society.")

Within this context, the prevailing and even consensual sociological premise and finding is that the economic system is a part or subsystem of and thus situated and implicated ('embedded') in and conditioned by the social system as the comprehensive whole, thus applying an holistic approach to the relations of economy and society. In a classic example, Comte (1983) posits that the 'various functions of the social economy' tend to be 'naturally implicated in relations of greater generality' constituting the social system, thus expressing the 'constant action of the whole upon the parts.' Echoing Comte, Pareto (1963[1916]) suggests that the economic system, constituted by logicorational actions motivated by 'tastes' and subjected to 'obstacles to the acquisition of economic values,' operates within the 'sociological system' deemed 'much more complicated' in virtue of being composed of both 'logical and nonlogical actions' induced by a wider set of 'residues (sentiments), derivations, interests, and proclivities.' Durkheim (1965a[1893]) proposes, in an influential proposition in economic sociology and social economics, that a commercial contract far from being 'sufficient unto itself' is 'possible' only due to a 'regulation' of an 'essentially social' character, because in such contracts not all elements are 'contractual,' thus suggesting the societal, notably institutional, bases or conditions of this and other market transactions. Evoking Pareto and Durkheim, for Parsons (1937) the economic system/concept only arises and operates, or is possible and understandable within 'social systems of action,' although being also applicable to the 'system of action of a particular individual' yielding 'Crusoe economics' as a fiction. In particular, Parsons (1951) characterizes wealth cum economic power as a 'lineally quantitative element or variable in the total equilibrium of social systems' in contrast to its political form as a nonlinear (zero-sum) variable.

Also, contemporary social systems theorists analyze the relationship between the economic and the social systems as that between a unit and a whole. Economy is considered the 'behavioral system of instrumental action' and 'technical control' (Habermas, 1971) within the total social system comprising also noninstrumental or noneconomic (political, communicative, and symbolic-cultural) actions (also, Alexander, 1998). For instance, the 'economic level of social systems' (Habermas, 2001) is exemplified by capitalism and communism during the Cold War, as well as varieties of capitalism during and after that period. In this respect, economy is characterized as both a particular 'social system' and a subsystem of the general social system (Luhmann, 1982). Based on its component of material resources and transactions, economy is deemed a 'closed self-referential system' as 'only' half of its equation and 'operational meaning' because it is also an open or opening subsystem of the social system in virtue of its functioning 'ultimately' taking place within or referring to the latter as its 'environment' (Luhmann, 1995). In this conception, the 'differentiation' of the economy as a particular system within the whole social system results from the 'interconnection of the conditions for closure and openness' because the 'unavoidable coupling of self-and-other-referential meaning references in all economic operations' necessitates definite social-systemic 'conditions' (Luhmann, 1995). Also, a contemporary Parsonian model treats economy as a 'functional subsystem' and thus with its own 'environment' consisting of the other subsystems of the total social system, while representing an 'ongoing solution to the problem of social adaptation' in the form of 'production of economic resources or wealth for the social system' (Fararo, 2001). In short, as leading contemporary economists admit, economy is an integral element, component unit of the social system (Arrow, 1994) within social systems theory (in contrast to 'pure' economics).

The relative significance of the economic system in the social system is determined and specified in two main alternative ways in sociological systems and related theory. In one rendition, economy represents the main subsystem and the prime causal factor of the social system as a whole, a position held by Marx, Tönnies, and most economists since Smith as well as 'rational choice' theorists. Marx argues that the 'social

structure and the State' evolve from of the economic 'life process of definite individuals' placed under 'definite material limits, presuppositions, and conditions independent of their will' (Marx and Engels, 1947[1847]). Arguably, the 'totality' of the relations of production making the 'economic structure of society' forms the 'real foundation' of polity ('legal and political superstructure') and culture ('social consciousness') (Marx, 1970[1859]). In general, for Marx's economic/conflict systems theory, orthodox economics and 'rational choice theory,' economy is the principal structural element and the explanatory variable of the social system.

Another alternative conception considers economy a relatively secondary subsystem and the causal effect or function of the social system, including political and cultural systems, a view characteristic of Comte, Simmel, Durkheim, Weber, Sorokin, Parsons, contemporary economic sociologists, social economists, etc. Comte (1983) and Durkheim (1965a[1893]) treat the 'social economy' as largely a secondary element of and determined by or implicated and embedded in the total social system, Simmel (1964[1908]) propounds that the 'form of economics, too' represents "merely a 'superstructure' (within) the purely sociological structure" contradicting Marx, while Weber (1968[1920]) states that an economic system crucially depends on 'protection by force' and thus on the 'political system.' Also, Sorokin (1957) and Parsons (1951) mostly regard economy as a subsystem of secondary or equal causal significance within the social system, especially in relation to the cultural system in the first theorist and the 'value-integration' system in the second. For instance, in Parsons' (1951, 1967) Adaptation, Goal-Attainment, Integration, Latent-Pattern-Maintenance (AGIL) model, economy (fulfilling the functional imperative of 'adaptation' A) is largely a secondary subsystem compared to the 'integrative system' (attaining system integration I) as the primary within the total social system and approximately of equal significance as polity (goal-attainment G) and culture (latent-pattern maintenance L). Generally, in Comte–Durkheim–Sorokin–Parsons' integrative and functional systems theory, economy represents mostly a subsystem of secondary relative significance and the dependent variable of the social system, in particular value/cultural systems.

Yet another alternative conception seeks to reconcile or integrate the previous two by treating economy as subject to historical and empirical variations in relative system significance and as both an explanatory factor and the dependent variable of the social system. Such a conception is especially characteristic for Weber (1968[1920]) in his main work *Economy and Society* and his followers, including to some degree Parsons in a book with the same title (Parsons and Smelser, 1956), as well as Simmel (1990[1900]) and Pareto (1963[1916]).

The Political System and the Social System

Another structural element or subsystem of the social system comprises polity, i.e., the political system. Sociological systems theory assumes and analyzes certain attributes, constituents, and consequences of polity analyzed, as economy, within the setting and functioning of the total social system in partial contrast to political science if the latter considers its subject as mostly a self-contained, autonomous structure vis-à-vis society.

An essential attribute or outcome of the political system is considered social regulation, direction, restraint, and order for public ends. Comte (1983) posits that the 'only object of any political system' its regulation of the 'spontaneous' social cooperation to 'expansion' in the function of directing such processes toward a 'determinate end,' especially government regulating the 'social economy' in its 'various functions' that are 'naturally implicated' in the social system of 'relations of greater generality.' Spencer (1969[1876–96]) proposes that political organization epitomized by government seeks to regulate 'affairs' in the social system through combining the 'actions of individuals' for common purposes (e.g., 'tribal or national offense and defense'), and restraining individual and groups 'in certain of their dealings with one another,' thus forming a specific 'part of social organization' performing 'directive and restraining functions for public ends.' In short, polity's main attribute or outcome in the social system is what Simmel (1990 [1900]) denotes the 'sociopolitical organization and order.'

Another crucial attribute or outcome of the political system is considered power or authority, although the latter is not necessarily limited to polity but generalized as social power or domination to the total social system, including economy. Comte (1983) suggests that 'every social power,' notably political 'authority,' derives from and is grounded on a 'corresponding assent of various individual wills' in connection with a collective, 'common action' rendering power its 'organ' initially and 'regulator' ultimately. Comte infers that all 'great power' develops only the 'prevalent disposition of the society,' conceivably the 'radical consensus proper to the social (system),' thus being legitimate domination in the sense of Weber. Weber (1968[1920]) famously classifies (ideal) types of political authority understood as legitimate power/domination into charismatic, traditional, and legal-rational, and also distinguishes between 'domination by virtue of a constellation of interests' (including monopoly) characterizing economy from 'domination by virtue of command' typifying polity. Parsons (1951) points out the 'double aspect' of social (and other action) systems, one being the 'problem of power relations,' another that of Hobbesian societal 'order,' both representing a 'well-marked set of emergent properties' of these systems in the form of 'political action elements.' More explicitly and systematically, contemporary conflict systems and related theory treats and depicts polity and all society as the 'system of organizational power' (Collins, 1975), i.e., of authority in 'imperatively coordinated associations,' including political as well as economic ones and others (Dahrendorf, 1959).

Yet another attribute and constituent of polity is considered law, i.e., the legal system. Tönnies (1955[1887]) emphasizes that a 'common and binding system of positive law, i.e., system of norms' represents an essential trait and component of the modern polity and (capitalist) Society overall such that the 'revolution in the social order' is followed by a 'gradual change of the law,' with contract becoming the 'basis of the entire system' sustained or modified by the conjunction of 'rational will' induced by 'interests' and the 'authoritative will of the state.' Weber (1968[1920]) defines law as consisting 'essentially in a consistent system of abstract rules' and treats the 'legal order' and the 'administrative system' (i.e., bureaucracy) as 'vital' to the rise and functioning of 'rational capitalism.'

Similarly, contemporary sociologists suggest that modern polity and society tends to create a 'subsystem' specializing in generating and enacting 'collectively binding decisions' in the form of an 'administrative state' (Habermas, 2001).

In sociological systems theory, types of political systems are contained or implied as particular cases in those of social system as general categories. Comte's (1983) typology of historical social systems contains that of political systems into the old 'theological-military' polity, including 'theocratic government,' as the 'conservative system' exerting 'retrograde tyranny,' and the new 'positive polity' as the liberal-democratic, with the intermediate case of the 'metaphysical polity' characterized with 'revolutionary anarchy.' In accordance with the 'fundamental law of social evolution,' Comte (1983) observes that the 'natural progress' of society (plus intelligence) tends to the 'complete elimination' of the theological-military and theocratic regime and predicts that the latter will 'never' again function as a 'basis for social order' instead based on the 'positive polity' that, while embracing 'all the essential aspects of the present state of civilization,' overcomes both 'retrograde tyranny' and 'revolutionary anarchy.' Mannheim (1956) divides political systems and ideologies into the non- or 'pre-emocratic authoritarian' system and mind and the modern 'democratic system,' specifically 'representative democracy' characterizing the Western 'governmental system,' and Dahrendorf (1959) describes the latter as the 'system of representation,' including 'electoral systems' and 'elaborate system of conflict regulation in the political sphere' as well as economy. Some contemporary sociologists (Habermas, 1973) retain the pre- or nondemocracy and democracy dichotomy suggesting that the 'positive value of the system of authority' can be realized only in the latter, namely, through the freedom of the 'polis' in the generic sense of a liberal-democratic political system.

As in the case of economy, sociological systems theory treats the relations between polity and the social system as those between a subsystem and a general system. Comte (1983) and Durkheim (1965a[1893]) consider polity, in particular the state, one of the integral elements (alongside economy) of the social system, thus a 'political society' (and 'economic society'). Marx and Engles (1947[1847]) treats the state, including systems of law, as the 'active, conscious, and official expression' of the 'structure of society,' above all its 'economic structure' constituted by the 'totality' of relations of production on the assumption that the latter 'in all ages' provides the 'basis of the State and the rest of the idealist superstructure.' In particular, he contends that the state represents the expression of class structure in that it arises and operates as the 'form' for asserting the 'common interests' of a 'ruling class' against other classes within the social system (Marx and Engles, 1947[1847]). Also, Pareto (1963[1916]) emphasizes that the 'system of government' in modern and premodern societies tends to be intimately linked with the 'character of governing class,' while both political and stratification systems being in a 'relationship of interdependence with all other social phenomena' within the 'sociological system.'

Contemporary systems theory continues treating polity or state as the subsystem of the 'whole social system' (Luhmann, 1995), while distinguishing the first from economy. According to such a distinction, the functional subsystem of politics shows 'no exact isomorphy' with that of economy for the reason that the 'communication medium of power' lacks the 'technical provision or integrative capacity of money' or wealth (Luhmann, 1995). In this account, while the 'use of power' not being strictly a 'political phenomenon' but extending in various ways and degrees into the whole social system, the 'concept of the state' primarily fulfills such a 'function' (Luhmann, 1995) through what Weber (1968[1920]) calls its 'monopoly' on the legitimate exercise of domination or force (Habermas, 2001; Smelser, 1997).

The Cultural System and the Social System

Culture also represents a structural element, subsystem of the social system, and in that sense a cultural system. Sociological systems theory generally characterizes culture as a system of ideas and thought arising and operating in and conditioned by the total social system. Saint-Simon (1964[1816]) registers 'systems of religions, politics, ethics, and education (and other) applications of the system of ideas' as essential characteristics and ingredients of culture also characterized by Comte (1983) as a 'system of ideas and conceptions,' including the 'educational system.' Similarly, Mannheim (1936) treats 'systems of ideas,' notably 'divergent' ideological or thought systems, including 'closed static systems of thought,' as fundamental cultural phenomena and the main subject matter of the sociology of culture and knowledge.

Relatedly, sociological systems theory regards culture as a system of values, ideals, and norms or rules. For Durkheim (1974[1924]), 'principal social phenomena,' notably culture, including religion, morality, and aesthetics, and even law and economy, constitute 'systems of values and hence ideals,' in particular a 'whole system of moral forces.' Also, Weber (1968 [1920]) points to a 'system of values' (e.g., an 'individualistic system of values') and a consequent 'system of norms and duties' with a binding force in a social system. Following Durkheim and Weber, Parsons (1937) adduces the 'existence of a common value system' and a resulting 'common system of normative rules' as the fundamental trait and element of the 'cultural system,' also composed of 'symbolic systems' premised on a 'cultural tradition' and values. Parsons (1951) particularly stresses the 'special relevance to the social system' of 'moral standards' thereby considered to be of the 'greatest direct importance' among 'value orientations.'

In sociological systems theory since Comte, Spencer, and Durkheim a particularly manifest and salient element or form of the cultural system is considered religion as a belief and value system, as Weber also emphasizes. Comte (1983) and Spencer (1969[1876–96]) analyze religious systems or institutions as the primary and original elements or forms of the cultural system, above all at its theological-military historical stage, while observing and predicting their ultimate demise and replacement by positive science due to scientific rationalism and progress and industrialization leading to their differentiation from political and other systems or institutions within the social system and so secularization. Elaborating on Comte and Spencer, Durkheim (1965b[1915]) analyzes the 'most primitive' religious system as that existing in a society with the least complex organization, suggesting that the 'first systems of representations' have 'religious origin.' Durkheim

(1965b[1915]) defines religion as 'a more or less complex system of myths, dogmas, rites, and ceremonies' with a certain unity, i.e., a 'system of cults' and a 'unified system of beliefs and practices' in relation to things, and emphasizing the 'immediate link between religious beliefs and the organization of society.' In turn, Weber (1968[1920]) focuses on analyzing comparative religious systems such as the 'great world religions' in interaction and interpenetration with the other elements of the social system, notably economy and polity. Like Durkheim and Weber, contemporary sociologists characterize religious and related belief systems as the 'idealized system of ends' (Alexander, 1998; Martin, 2002).

Another related pertinent element or form of the cultural system has considered morality as a system of ethical values and norms of human behavior in society. Durkheim (1974[1924]) defines morality as a 'system of rules of conduct' that is conditioned by and arises within the 'total (social) system' to the effect that changes in social structure necessitate a 'change in morals (as) a system of precepts.' Following Durkheim, Parsons (1951) considers 'moral standards' to be that dimension of 'value orientation' and by implication culture overall that is the 'greatest direct importance' because of their 'special relevance to the social system.'

Other elements or forms of the cultural system include systems of classification, symbolic systems, ideological systems, scientific-educational systems, etc. In particular, Durkheim and Mauss (1903) define classifications of categories as 'systems of hierarchized notions' ordered in 'fixed relations,' and grounded in and representing the 'classification of men' within the social system, so that the 'entire system of concepts' expresses the nature and structure of society and how it views the 'world,' thus 'logical hierarchy' being 'only another aspect of social hierarchy,' i.e., 'dominating and subordinated' groups. Similarly, Mannheim (1936) focuses on 'ideological systems' and their basis in and determination by the social system, especially 'collective action' and 'class stratification.' Contemporary sociologists also emphasize 'systems of classification' and 'symbolic systems' regarded as being 'always determined in several respects at once' (polysemy) by the social system, above 'material conditions' (Bourdieu, 1988), particularly stressing the 'prevailing symbolic system' and its social-systemic determinants and effects (Habermas, 1971). Likewise, systems theorists since Comte regard the educational system as the relevant component of the cultural system as well as that of social stratification (Dahrendorf, 1959; Bourdieu, 1988), and suggest that science and generally knowledge provides the 'solution of system problems in general' rather than the 'gratification of immediately empirical needs' (Habermas, 1971).

Like economic and political systems, types of cultural system generally correspond to and are implied in those of social system, with the classifications of the latter implying those of the former as the subsystem. Tönnies (1955[1887]) observes that in the modern social system the 'entire culture' has become a cultural system and 'civilization of state and of capitalism' premised on a moral 'system of conventional rules' in sharp contrast to morality as a 'purely ideal or mental system of norms for community life.' Simmel (1964[1908]) distinguishes a 'highly differentiated scientific culture,' 'intellectual culture,' and 'economic culture' as particular cultural systems or elements mostly within the modern social system.

Sociological systems theory typically considers the relations between the cultural system and the social system as those between a subsystem and a general system, although sometimes using the two terms interchangeably or as a composite term, e.g., 'sociocultural systems' (Sorokin, 1957), or even treating 'culture' as apart from and beyond the social system in action terms (Parsons, 1937). The general theoretical premise or empirical generalization is that only the social system either as a human society or group can and does create, have, and sustain culture as a system of ideas, values, norms, and symbols, including religious, moral, classification, symbolic, and scientific-educational systems, as especially Durkheimian sociology emphasizes (also, Mannheim, 1936; Merton, 1968; Sorokin, 1957).

In particular, system theorists analyze the relations of the cultural system to such other partial social systems as economy, stratification, polity, etc. One approach treats culture as mostly determined by the economic and class systems, and thus as the dependent variable. This is exemplified by Marx's (1970[1859]) proposition that the 'economic structure of society' determines 'cultural development,' in particular the class being the 'ruling material force of society' tends to be simultaneously its 'ruling intellectual force.' Also, contemporary conflict system theorists emphasize 'the objective relations between the system of economic production' and the 'system producing the producers,' including schools and family (Bourdieu, 1988). In this relationship 'material conditions' are the structuring and these cultural elements (or habitus) a 'structured' variable, and constituting a 'system of mechanisms' for the near-automatic 'reproduction of the established order by its own motion,' thus allowing the dominant class to assert its domination by simply letting the 'system' operate by 'its own course' (Bourdieu, 1988). In short, the outcome of the impact of economic and class structure on culture is a 'system of class culture' (Collins, 1975).

Another alternative approach instead regards culture (also) as a determinant of economic and other systems within the social system, and so an explanatory variable. This is exemplified by Simmel's (1990[1900]) assumption that money forms the 'pinnacle of a cultural historical series of developments' determining its 'direction' and thus that of corollary economic phenomena (commercial exchange, value, price, market, etc.). Notably, this approach is epitomized by Weber's (1968[1920], 1976[1905]) famous analysis of the influence of religion on economy, in particular of the world religions (above all, ascetic Protestantism) on the rise and development of capitalism.

The Civil System and the Social System

Yet another structural element, i.e., subsystem of the social system consists of civil society or societal community, also termed the (mostly) individual, private, and autonomous sphere of life, the 'lifeworld' (Alexander, 1998; Giddens, 1984; Habermas, 2001). Early sociological and philosophical definitions especially define and analyze civil society in counter-distinction and in part disjuncture from polity, specifically state as the public realm, but in association and even partial equation with economy, specifically private commercial and

other economic activity. Following Hegel, Marx and Engles (1947[1847]) defines civil society as the 'form of intercourse,' specifically the 'whole material intercourse of individuals' driven by 'private interest' and 'determined' as well as 'determining' the forces of production at a 'definite stage' of their development – i.e., only arising with 'bourgeoisie' – thus the 'social organization' developing from 'production and commerce,' so its 'anatomy' lies in 'political economy' as the 'basis of the modern State.' Following Marx, Tönnies (1955 [1887]) suggests that the basis of Civil Society (in the sense of modern bourgeois capitalism) is 'general commercial exchange.' Simmel (1964[1908]) conceptualizes civil society largely in social, particularly moral, terms, as the sphere of sociability emerging as a 'very peculiar sociological structure.' This anticipates the contemporary prevalent conception of civil society, and envisions that its 'minimum of ethical, peaceful behavior' as the necessary condition of its existence is not equal to but transcends the 'criminal code' (Simmel, 1964[1908]).

Most contemporary conceptions consider civil society a distinct social subsystem not only in relation to polity/state but also to economy/market, i.e., both a noneconomic and a nonpolitical sphere of life, thus qualifying Marx and following Simmel. Parsons (1967) treats civil society, also termed 'societal community,' as the 'integrative system' that is functionally differentiated from (although in interaction with) economy and polity, as well as culture, within the total social system (also, Fararo, 1989; Munch, 1990), particularly, as Merton (1968) also suggests, generating or affecting the 'motivation of individuals involved in a social system.' In this context, Parsons' societal community is regarded as introducing a 'fourth' subsystem or sphere within the social system indicating a 'world' featuring the 'subjectivity of the lifeworld,' joined with the 'abstraction of more highly rationalized systemic spheres' (Alexander, 1998). Other contemporary sociologists conceive civil society or the lifeworld as involving the 'normative structures (values and institutions) of society' (Habermas, 1975) and providing individuals with a 'shared store of cultural knowledge, socialization patterns, values, and norms' (Habermas, 2001), thus being almost equated or most closely related to culture within the social system. In sum, civil society is commonly defined as a 'private sphere' of life in separation from and in tension with – although historically the creation of and with origins in – the 'public sphere of the state' (Giddens, 1984), i.e., 'an informal social order' mostly nondominated by 'large-scale coercive' political as well as economic structures and instead creates and sustains through 'various forms of communication and reciprocity' (Alexander, 1998).

Consequently, civil society is considered to essentially differ from, even if related to, other social systems, especially economy and polity. In this view, the 'rationalization of the lifeworld' in modern society differs from 'rationalizing economic or administrative' systems and activities, instead encompassing 'cultural traditions, socialization of individuals and social integration' in contrast to economy and politics as 'functionally integrated' and 'self-regulating systems' regulated by 'money and administrative power' (Habermas, 2001). Moreover, it is argued that the 'balance' within the social system becomes negative when economic-political systems trespass into the 'lifeworld' in the sense that the 'invasion' of the latter by 'exchange relations and bureaucratic regulation' results in various 'social pathologies' (Habermas, 2001). In short, in the modern social system a strong civil society is deemed a necessary condition for 'effective democratic government' as well as a 'well-functioning market system' (Giddens, 2000). The preceding structural elements or subsystems of the social system are summarized in **Table 1**.

Table 1 Elements/subsystems of the social system

Economy	Polity
Division of labor, wealth, market	Public ends, legitimate power, law
Culture	Civil society
Ideas, values, norms	Private sphere, lifeworld

Social Work and Disasters

Abstract

There has been an increase in the incidence and impact of both natural and human-induced disasters. Poverty always determines the relative severity of impact. Social workers' skills and experience are very relevant for disaster work, including concern for human rights, protection of children and vulnerable people, and social inclusion of those affected. Psychosocial and community recovery interventions are needed. The needs of workers are often similar to those they are supporting and must be addressed. Cultural competence must inform program delivery.

Introduction

Social workers' skills and experience are highly relevant for multidisciplinary disaster work. Of particular significance are their understanding of human behavior, emphasis on 'person-in-environment,' experience in community work and program planning, and recognition of the value of advocacy and social justice. With the apparent increase in and awareness of natural, technological, and human-induced disasters, the need for all social workers and other helping professionals to become aware of this work is increasing (Cronin and Ryan, 2010). The world social work community has recognized disaster response as a priority area for social work education and practice (International Federation of Social Workers et al., 2012).

What Are Disasters?

The term 'disaster' is variously defined by authors from different disciplines and humanitarian communities. The definitions all have political, ideological, cultural, and other biases. The more research is undertaken, the more definitions are devised. The United Nations defines disaster as "a serious disruption of the functioning of a community or a society involving widespread human, material, economic or environmental losses and impacts, which exceeds the ability of the affected community or society to cope using its own resources" (UN, 2009: p. 9).

Disasters are often described as resulting from (1) exposure to a hazard, (2) preexisting conditions of vulnerability, and (3) insufficient capacity or measures to reduce or cope with the potential negative consequences (UNISDR, 2009: p. 9).

$$\text{Disaster} = \text{hazard} \times \text{exposure} \times \frac{\text{vulnerability}}{\text{manageability}}$$

(Wisner, 2004).

The definition implies a sudden, overwhelming, and unforeseen event. At the community level, it can be a flood, fire, earthquake, loss of incomes, disease epidemic, or displacement through conflict. At the family level, a disaster could result in a major illness, death, economic, or social hardship. When occurring across a region, a large number of people can be affected.

Disasters can be categorized as either natural or human-induced occurrences. Natural disasters include weather phenomena (such as tropical storms, extreme cold or heat, high winds, drought), floods, avalanches, earthquakes, tsunamis, wild fires, landslides, and volcanic eruptions. Human-induced disasters include transportation incidents; industrial accidents; release of hazardous materials; building collapses; and extreme events such as famine, political conflict, and climate change. However, this distinction can be less clear-cut than it seems, with the severity of the impact of the disaster frequently contingent on human factors (e.g., socioeconomic status).

The Disaster Cycle

The characteristics of disaster work are often presented as a four-stage cycle: mitigation, preparedness, response, and recovery (National Governor's Association, 1979). Each phase requires distinct tools, strategies, and resources. Social work can be involved at each stage by contributing to strategy and policy development as well as by direct work with individuals and local communities.

Source: unknown.

Mitigation: 'the lessening or limitation of the adverse impacts of hazards and related disasters.' Mitigation measures encompass engineering techniques and hazard-resistant construction as well as improved environmental policies and public awareness (UNISDR, 2009: p. 19). Mitigation involves steps to reduce vulnerability to disaster impacts, such as injuries and loss of life and property, and other efforts to make the community more resilient to catastrophic event, but the avoidance of emotional trauma and community disruption are also significant consequences.

Preparedness: "the knowledge and capacities developed by governments, professional response and recovery organizations, communities and individuals to anticipate, respond to and recover from the impacts of likely, imminent, or current hazard events or conditions" (UNISDR, 2009: p. 21). Preparedness focuses on understanding how a disaster might affect the community and how education, outreach, and training can build capacity to respond to and recover from a disaster. This may include engaging the business community and community groups and predisaster strategic planning.

Response: 'the provision of emergency services and public assistance during or immediately after a disaster to save lives, reduce health impacts, ensure public safety, and meet the basic subsistence needs of the people affected.' Disaster response or 'disaster relief' is predominantly focused on immediate and short-term needs (UNISDR, 2009: p. 24). Response addresses the immediate threats presented by the disaster, including saving lives, meeting humanitarian needs (food, shelter, clothing, public health, and safety), cleanup, damage assessment, and the start of resource distribution. As the response period progresses, focus shifts from immediate emergency issues to conducting repairs, restoring utilities, establishing operations for public services, and finishing the cleanup.

Disasters frequently reveal and exacerbate weak economic and social infrastructures and development, with significant gaps in organizational capacity, staff, and resources. For effective response and recovery, economic development agencies and stakeholders may need additional staff, capacity-building assistance, and social stability. This is illustrated in the contrast between the impact of the earthquakes in Chile and Haiti, the former making a rapid recovery thanks to effective planning and developed public services, while the latter had very weak social infrastructures and ineffective planning and is still struggling after several years of international aid (Arbour et al., 2011).

Recovery: 'the restoration and improvement of facilities, livelihoods, and living conditions of disaster-affected communities, including efforts to reduce disaster risk factors.' The recovery task of rehabilitation and reconstruction begins soon after the initial response phase, and is ideally based on preexisting strategies and policies that facilitate institutional responsibilities for recovery action and enable public participation (UNISDR, 2009: p. 23).

The recovery phase of disaster can be broken into two periods. The short-term phase typically lasts from 6 to 12 months and involves delivering immediate services. The long-term phase, which can be decades long, requires thoughtful strategic planning and action to address more serious or permanent impacts of a disaster. Investment in social and economic development capacity building becomes essential to foster economic diversification, attain new resources, build new partnerships, and implement effective recovery strategies and tactics. Communities must access and deploy a range of public and private resources to enable long-term recovery.

Human Impact of Disasters

Demographics

There is a strong interrelation between the severity of impact of disasters and poverty. Poorer people live in the most drought, flood, and extreme-weather prone regions and suffer most when catastrophe occurs (UNDP, 2012). Ninety-five percent of disaster fatalities occur in developing countries; the likelihood of death in a disaster is four times greater for people in lowest-income countries than those living in high-income countries (World Bank, 2001: p. 171). Disasters put hard-won development achievements at risk, reversing economic growth and progress toward the elimination of poverty, cause environmental damage, and result in human suffering. Disasters have killed more than 1.3 million people and affected an average of 220 million per year over the past two decades. In 2011, 106 million people were affected by floods, 60 million were affected by drought, mainly in the Horn of Africa, and almost 30 000 were killed. Disasters cost the world economy more than $380 billion in 2001 (UNDP, 2012).

Disasters have a differential impact on men and women, reflecting the distinct roles of the two sexes in political, economic, and social life (Pittaway et al., 2007; Zetter, 2012). In countries where gender discrimination is tolerated, women and girls are particularly vulnerable. Not only is the percentage of women and girls who die higher in these counties, but the incidence of gender-based violence – including rape, human trafficking, and domestic abuse – also increases exponentially during and after disasters. Most disasters place an undue burden on women and girls who are responsible for unpaid work such as providing care, water, and food for households (Zetter, 2012: p. 13). In the case of Hurricane Katrina in New Orleans, USA, most of those trapped were African-American women and their children, the poorest demographic group in that region (United Nations Development Program, 2010). Similarly, 32% of Nicaraguan farming households headed by females did not plant the following year, compared to 23% of male-headed farming households (Bradshaw, 2004: p. 26).

Social Implications of Disasters

On a long-term average, 184 deaths per day are recorded worldwide due to natural hazards. Most of these occur in countries that rank low on the Human Development Index (UNDP, 2011: p. 10). For every person killed, around 3000 more are affected (UNDP, 2011: p. 14) and become severely impoverished through the destruction of personal assets, damage to health and education infrastructure, and loss of

drinking water and sanitation. If the disaster is compounded by casualties from HIV/AIDS or armed conflict, social and economic structures can be destabilized. Natural disasters in poorer countries frequently result in major migrations or population displacement with far-reaching social and political consequences.

'Environmental refugee' became a more frequently used term in the 1990s, referring to people forced to leave homes due to natural disasters or environmental reasons. However, environmental problems never appear in isolation; their interconnection with other emergencies resulting from social or political factors results in the great number of refugees (Zetter, 2012: p. 20). The United Nations Environment Program estimates that there are 22–24 million environmental refugees (Biermann, 2001: p. 24). Most of these migrants move between developing countries. For example, each year, thousands of inhabitants of Bangladesh go to India due to heavy flooding (p. 24), often starting a new life in surroundings that are completely unprepared to accommodate them or are inappropriate for settlement. Similarly, the large number of environmental refugees in the Horn of Africa is not primarily a consequence of drought, which affected 60 million, but due to weak governments, political and military conflicts between competing factions, the destruction of traditional coping mechanisms, and inadequate infrastructures, thus resulting in serious political destabilization across the region (Zetter, 2012: pp. 21–23).

The political, social, and economic challenges facing host countries in coping with these refugees are often unmanageable (Zetter, 2012: pp. 19–21). Extreme poverty can result from disaster-related migration because the refugees lack every kind of social service, including health care, schools, and access to safe drinking water. Traditional family structures, once an important form of support during crisis, are destroyed. Groups of citizens that previously were not considered poor can fall into poverty due to forced migration and the political management of refugees.

Economic Implications of Disasters

Over the last 50 years, the global cost of natural disasters has increased 14-fold, with weather-related and natural disasters accounting for two-thirds of all losses (Guha-Sapir et al., 2004: p. 13). Annual economic losses due to natural disasters in the last decade reached an estimated $55 billion, with a high percentage of losses in infrastructure (German Federal Ministry for Economic Co-operation and Development (BMZ), 2001). While absolute levels of economic loss are greater in developed countries due to the far higher density and cost of infrastructure and production levels, less-developed countries suffer higher levels of relative loss when seen as the proportion of gross domestic product (UNDP, 2004: p. 20).

Developing countries are not only facing the potential of more frequent weather-related events. Rapid urbanization, the increased concentration of assets, environmental degradation, and other factors are also increasing the vulnerability of poor communities to disaster impacts. By 2025, roughly two-third of the world's inhabitants and the vast majority of wealth will be concentrated in urban centers. Many of the world's megacities (populations exceeding 10 million) are already situated in locations prone to major earthquakes and severe droughts, and along flood-prone coastlines, where the impacts of extreme climatic events and sea-level rises pose a greater risk of disasters. Today, more than half the global population resides in urban areas. Especially vulnerable to natural disasters are megacities like Jakarta, Istanbul, Buenos Aires, Athens, Saõ Paulo, and Mexico City (UNISDR, 2012). Urbanization in relatively smaller cities also increases risk – particularly in regions where infrastructures and institutions are ill equipped to cope with disasters. The vulnerability of this new generation of urbanites will become a defining theme of disaster risk in the coming decades (Zetter, 2012: p. 113).

Economic implications of disasters are conventionally categorized as direct, indirect, and secondary losses. Direct losses include loss of life and physical assets, damage to infrastructure, and loss of inventory and agricultural produce. Indirect losses include those caused by disruption of the flow of goods and services, like reduced opportunities for generating income. Examples of indirect costs include loss of earnings; unemployment; loss of productivity due to death, illness, and injuries; and increased public finance expenditure (Guha-Sapir et al., 2004: pp. 38–45).

The final category includes impact on macroeconomic variables such as economic growth, state budget levels, national indebtedness, and inflation. The secondary effects of disasters are important because these can have significant impact on long-term human economic development and social stability (International Debates, 2005).

Political Implications of Disasters

Disasters can evoke severe governance problems. The processes through which citizens articulate their interests and exercise their legal rights – an important aspect of the political dimension of disaster – can deteriorate, especially where political rights are poorly recognized. Inquiry into the economic aspect of governance reveals that financial decisions made during disaster and the reconstruction period have major implications for poverty and quality of life. Under time and financial pressures, politicians are likely to abandon carefully developed budget plans and overturn long-term development programs to release resources for immediate emergency aid. This money is often used for the recovery of one group at the expense of others. Economically poor groups with little access to decision making are likely to be left out. Gender and other fundamental social issues are often disregarded. The result can be the reaffirmation of existing inequalities (UNDP, 2004: p. 21).

Social Work and Disasters

Social work in the disaster process draws on methods and practice most of which are common to other members of the multidisciplinary team. These are described below. However, social work also contributes some distinct perspectives which, while not unique to social work, do have a particular emphasis arising from its core professional functions (Dominelli, 2010).

Concern for Human Rights

The response phase of disaster response is usually focused on meeting fundamental needs for safety, security, food, and shelter. In extreme situations the protection of life is the main concern. This can lead to expedient decisions under extreme pressure, which appear not to allow for consideration of other human rights, e.g., the right to family life, freedom from exploitation, and participation. Study of specific examples suggests that a lack of attention to human rights can result in unfair distribution of aid, exploitation of vulnerable people, and placing children and others at further risk (Klasing et al., 2011). Social workers have particular experience of situations where vulnerable people are at risk of losing their rights and of mediating in family and community situations where there are competing human rights (Banks and Nøhr, 2011: Case 2.1). These skills are important both in the immediate response and as a foundation for recovery (Zetter, 2012: pp. 47–71).

Populations at Risk – Protection of Children and Vulnerable People

Social work training and experience includes a focus on those who are most vulnerable and/or in need of protection. Social workers offer particular perspectives on disaster response involving vulnerable groups. Within a community affected by disaster, people can be seen as suffering primary, secondary, or nondirect impacts. The primary group comprises those who have experienced direct physical, material, and personal losses from the disaster. The secondary group involves those who have witnessed the destruction of the disaster, but have not directly experienced the specific impact. The nondirect category refers to those who were not directly affected by the disaster, but who suffer distress and uncertainty over the safety and well-being of family and friends.

Among the categories of those affected by disaster are vulnerable populations of concern: poor people; older persons; persons with disabilities; people who are isolated, institutionalized, or otherwise at risk; and all exposed children. These populations may require special attention during preparedness, immediate relief, and recovery activities (Congress et al., 2010; Dominelli, 2012; Smith et al., 2012).

The risks faced by those in disaster situations have been recognized in operational guidelines published by the United Nations (Inter-Agency Standing Committee, 2007). Risks can include the trafficking of vulnerable women and orphaned children on the pretext of 'rescuing' them, thereby resulting in sexual exploitation, virtual or actual slavery, or illegal adoption. Well-meaning, short-term 'rescue' activities can also cause long-term damage, for example, by misinterpreting the significance of symptoms of ill-health or removing children without parental knowledge or consent or preventing the reunification of families (Zetter, 2012: pp. 68–70). Social workers bring experience of handling such dilemmas.

Values and Ethics – Social Inclusion

Humanitarian workers share a humanitarian ethos or value system, based on respecting individual integrity, recognizing community order, and promoting human rights (e.g., International Federation of Red Cross and Red Crescent Societies, 1965; International Federation of Social Workers and International Association of Schools of Social Work, 2004). Social work places emphasis on self-determination and working 'with' people (rather than doing things to them). This approach encourages the active involvement ('social inclusion') of those involved in planning and deciding actions, something which UN agencies recognize has frequently been absent in the response to major disasters (Zervaas, 2007).

Psychosocial Interventions

Psychosocial interventions are immediate and delivered by a range of professionals, including social workers, and other mental health professionals. Community referrals are made for those with long-term needs. Interventions are comparable in small or large disasters. The micro practice interventions fall into the following categories: psychological first aid (PFA), crisis intervention, assessment, casualty support, advocacy, outreach, and staff support (Cronin and Ryan, 2010).

Psychosocial and mental health support can be both preventative, decreasing the risk of developing mental health issues, and therapeutic, helping individuals and communities to overcome and deal with psychosocial problems resulting from the disaster.

Psychological First Aid

PFA is the cornerstone of support. The concept of PFA for individuals exposed to highly traumatic events has been used in the field of crisis and disaster management for years (Reyes, 2006). Similar to medical first aid, PFA involves providing immediate care, by attending to the biopsychosocial needs of those affected. It is practical and proactive and should not be confused with psychological assessment or treatment, only provided by trained mental health professionals.

PFA includes provision of basic care, comfort, and support during and in the immediate aftermath of disasters. It is designed for delivery by mental health and other disaster response workers who provide early assistance to affected communities.

PFA includes four broad goals: (1) to relieve physical and emotional suffering, (2) to improve short-term functioning, (3) to help course of recovery, and (4) to provide linkage to critical resources (Halpern and Tramontin, 2007: pp. 203–204). PFA helps stabilize persons in distress by ensuring safety and providing assistance in meeting simple needs.

Helping people to notify family members, making arrangements for child care, and contacting social service agencies for needed assistance can help stabilize individuals in crisis. Validating thoughts and feelings regarding their experience and promoting efficacy can support steps toward healing. Aiding clients in connecting to their natural support systems can be a critical intervention. For those without any supports, disaster mental health workers will either stay with the client or check in often to establish a sense of connection so the client does not feel isolated.

Clients are often desperate for information from authorities. They often ask questions such as when they can

return, whether a loved one has been found or identified, or how to recover a pet that was left behind. The period of waiting for information can be agonizing, and although disaster mental health workers do not directly provide information that law enforcement and governmental agencies are responsible for, they do advocate for official briefing updates for clients.

Crisis Intervention

Crisis intervention is the provision of emergency psychological care to victims to assist them in returning to an adaptive level of functioning and to prevent or mitigate the potential negative impact of psychological trauma (Everly and Mitchell, 1999). Crisis intervention procedures have evolved from studies of grieving conducted by Erich Lindemann (1994) in the aftermath of a nightclub fire.

An individual is perceived to be in crisis if he or she has experienced a meaningful and threatening event; if he or she has increased fear, tension, or confusion; and if usual coping mechanisms are not effective in alleviating the stress symptoms. Crisis intervention aims to moderate the emotional state and help the individual find adaptive solutions (Roberts, 2000). This is best exemplified when a worker helps a client to process and manage emotionality that is interfering with being able to engage in disaster recovery planning and activity. Crisis intervention techniques involve the quick establishment of rapport, functional assessment, psychoeducation on stress symptoms and coping strategies, problem solving, the development of an action plan, and referral for follow-up mental health treatment as needed.

Assessment

Assessments play a critical role in determining what psychosocial or mental health interventions are needed. Before planning can begin, it is necessary to find out what has happened and how people have been affected. The goal of screening and assessment is to evaluate mental health functioning and identify the appropriate intervention or referral. The task is the usual informed assessment and decision making that one would make with any person – watching for symptoms, intervening as appropriate, and dealing with the most severe cases first (Cronin and Ryan, 2010). When large numbers of individuals are affected and only a limited number of responders are available, the ability to perform rapid triage becomes crucial. The greater the degree of exposure to the disaster or reaction intensity, the higher the priority for immediate disaster mental health contact.

For the majority of those affected by disaster, early assessment and intervention will be unnecessary. Studies have shown that, even in extreme disasters, the majority of people do not become incapable of functioning and usually make a full psychosocial recovery. Resilience and coping are probably the most common reactions seen following disaster (Ursano et al., 1996). For individuals experiencing symptoms beyond what is expected from extreme stress due to a disaster – such as psychosis, suicidal or homicidal ideation, or major depression – a prompt mental health assessment and referral for immediate acute care is warranted.

Casualty Support

All disaster work requires the act of compassionate presence, the ability to be present with those suffering, and to be of comfort without trying to fix or provide answers (Berliner et al., 2009). To stand with another human being experiencing their worst moments, so that they do not suffer alone, is a humble and sacred task. Providing compassionate presence is critical when mental health interventions include casualty support for the loved ones of victims missing or deceased or for those who have suffered serious physical injuries, along with their families.

While disaster mental health workers do not make death notifications, they may accompany law enforcement personnel or medical examiner or coroner for the purposes of providing support. Families and friends of those lost or feared lost in a disaster require special consideration. Mental health workers support these individuals in private areas, whenever possible. Compassionate presence while loved ones wait for confirmation of death creates an invaluable support system that continues as the mental health worker accompanies family to the death notification.

Advocacy and Outreach

Disaster mental health workers are often able to advocate for client needs at disaster service sites. Advocacy can include asking officials when the next client briefing will be, requesting specific meals for populations with dietary or religious restrictions, ensuring that the disaster response is culturally competent, and handling any special needs situations.

Disaster mental health workers also serve on outreach teams that access affected communities, going door-to-door to check on those who may not have been seen at service centers that open to meet the needs of individuals during disasters. Workers may also reach out to those in hospitals (Cronin and Ryan, 2010).

Community Engagement

People usually share the experience of disasters with others who may be family, friends, or neighbors – or frequently strangers. It is necessary to respond to both individual and group needs in all four stages of a disaster. Effective programs and services integrate and address multiple levels, including community-level interventions, drawing on local coping strategies, and community resources (von Peter, 2009). For many people affected by disaster, being able to contribute to the recovery provides an immediate path to personal stability and resilience. Communities in less-developed regions are often self-sustaining; local economies and skills can be identified and reenergized. Those in more developed situations can use networking skills and community capacity to engage in recovery. Social workers can play a facilitating and supportive

role, for example, identifying and strengthening community 'leaders' and helping those affected to develop recovery strategies.

Staff and Peer Support

Volunteers and staff are vulnerable to stress by virtue of their work and the circumstances in which they do it. Staff and volunteers are often poorly prepared for their own emotional reactions to providing care and relief to others. Volunteers may work long hours in challenging emergency environments, often putting aside their own needs. At the end of the day, they often feel inadequate to help beneficiaries with the tragedy they are facing. Additionally, as members of affected communities, staff and volunteers often work close to home and may experience the same losses and grief in their families and communities as the beneficiaries they are supporting. Basic first aid training or being part of a disaster response team is not enough to prepare volunteers for these experiences.

Most disaster workers experience mild, normal stress reactions. Several studies indicate that one out of every three disaster workers at some point experiences severe stress symptoms (Marmar et al., 1996; Gibson and Iwaniec, 2003; Fullerton et al., 2004; Reid et al., 2005; Young et al., 2007).

The well-known concept of stress was defined by Selye (1956) as the nonspecific response of the human body to any demand made upon it. Figley (1995) describes compassion stress as a natural outcome of knowing about trauma experienced by a client rather than as a pathological process. The symptoms of compassion stress can include helplessness, confusion, and isolation. When compassion stress is ongoing and severe it can become 'compassion fatigue,' defined as "a state of exhaustion and dysfunction, biologically, physiologically, and emotionally, as a result of prolonged exposure to compassion stress" (Figley, 1995: p. 11).

Disaster mental health workers have a key role in maintaining a stable workforce during prolonged disaster operations. Staff and volunteers can be supported at key points to reduce the likelihood of developing stress-related problems. The primary intervention consists of good, solid information about the tasks at hand and about stress and coping with emotional reactions to difficult situations. Such information prepares helpers to detect their own reactions and offers options for self-care and peer support. Appraisal and recognition from others that they and their work are valued are essential.

The needs of volunteers and staff are often similar to the needs of those they are supporting. A supportive environment is a crucial factor in minimizing stress. This can be achieved by providing accessible guidance and support from managers and peers, by creating an organizational culture where people can talk openly and share problems without fearing consequences, by arranging regular meetings which bring all staff and/or volunteers together and foster a feeling of belonging to a team, and by respecting the principle of confidentiality so that people feel it is safe to talk about stress and seek help.

Peer support means offering assistance to someone at the same level as the supporter, enabling staff and volunteers to share their knowledge, perspectives, and experiences for the benefit of one another. The principles are generally the same as for PFA and supportive communication. There is evidence that an active, supportive approach to stressful situations facilitates successful coping. Allowing someone to talk about reactions and feelings facilitates coping and helps the individual to deal with stressful situations. The peer supporter provides support only and does not become a counselor. Peer supporters provide short-term assistance and do not replace professional help (IFRC-CPS, 2009: pp. 96–97).

Cultural Implications

Social workers deal with the psychosocial impact of a disaster on individuals, families, and communities. Humans respond to the stress of a disaster in a variety of ways, influenced by many factors: beliefs and religion, age, gender, sexual orientation, ability, education, financial resources, communication experience among others. Some of those influences can be seen as cultural. Providing culturally competent services to those affected requires action before, during, and after a disaster. Creating culturally competent environments requires more than recruiting bilingual and bicultural workers, sponsoring diversity workshops, or hiring a 'token' racial or ethnic minority group representative (IFRC, 1994).

Culture is expressed through shared customs, values, social rules of behavior, rituals and traditions, and perceptions of human nature and natural events. Cultural competence must be a part of the program values, included in the program's mission statement, and encouraged in attitudes, policies, and practices at every level (e.g., Dominelli, 1996; Weaver, 1999; Council of Europe, 2011).

To develop culturally competent programs and services, planners must assess and understand the community's composition; identify culture-related needs of the community; be knowledgeable about formal and informal community institutions that can help meet diverse psychosocial needs; gather information from and establish working relationships with trusted organizations, service providers, and cultural group leaders; and anticipate and identify solutions to cultural problems that may arise (Myers, 1994).

Concluding Observations

There has been an increase in the incidence and impact of both natural and human-induced disasters. While more disasters and the highest financial costs are reported in the developed world, poverty always determines the relative severity of impact on individuals and communities. Investment in disaster preparedness has a social and economic benefit. Social workers' skills and experience are very relevant for disaster work, including concern for human rights, protection of children and vulnerable people, and social inclusion of those affected. Psychosocial and community recovery interventions are needed. The impact of disasters on workers is usually significant; their needs are often similar to those they are supporting and must be addressed. The nature of the response must take account of local culture and local social systems. Social workers, by training and experience, are

well placed to make a distinctive contribution at all stages of disaster work.

Social Work and Psychodynamic Thought

Jerrold R Brandell, School of Social Work, Wayne State University, Detroit, MI, USA
Laura J George, Washington Center for Psychoanalysis, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews psychoanalytic theories of development and psychopathology, different models of psychodynamic treatment used in clinical social work practice, and several major critiques of psychodynamic thinking. Psychodynamic social work is defined as any psychoanalytically informed social work practice that makes selective use of psychoanalytic ideas about human development, pathogenesis, and treatment. The psychoanalysis of today, while preserving important traditions spanning over 100 years, is a far more sophisticated, complex, and scientifically elaborated body of knowledge. Its development argues convincingly for a reappraisal of what contemporary psychoanalytic theory and practice knowledge have to offer the clinical social work field.

Introduction

The first portion of this article reviews psychoanalytic theories of human development, psychopathology, and treatment used in clinical social work practice. Psychodynamic social work is here defined as any psychoanalytically informed social work practice that makes selective use of psychoanalytic ideas about human development, pathogenesis, and treatment. In the second portion, we consider five major critiques of psychodynamic thinking.

Psychodynamic Conceptions of Mind, Psychopathology, and Treatment

Conceptions of Mind in Classical Freudian Theory

Prior to the introduction of the structural model in 1923, Freud's understanding of human nature was that the unconscious mind contained instinctual drives (Freud identified two drives or instincts, sex (libido) and aggression, to which he ultimately attributed the most basic internal motivations for behavior), which are biologically based motivational systems seeking satisfaction in behaviors. According to this model, intrapsychic conflicts arise when unconscious desires press for representation in the conscious mind, but are prevented from achieving it by repression (a defense mechanism that excludes a psychologically painful or conflict-laden idea from conscious awareness. Repression is regarded as the prototype for defenses insofar as all defensive operations are designed to protect the self from conscious exposure to objectionable ideas, impulses, attitudes, and wishes. In Freud's early writings, repression was used more or less interchangeably and synonymously with the concept of defense, although as other defenses were elaborated, it came to be more narrowly defined). In this framework, accumulating tension that has not been permitted release, results in symptoms. Symptom relief occurs when disassociated mental contents are reconnected by breaking through the repression barrier, in effect making the unconscious conscious.

Freud also postulated four stages of psychosexual development based on erogenous zones. If there is too much trauma or frustration, a child cannot move to the next stage of development. The stages include the pleasurable sensations of the oral, anal, phallic, and genital phases. The phallic phase becomes important as the child moves toward resolution of the Oedipus complex, when there is simultaneous renunciation of the child's desire for sexual possession of the opposite-sex parent and for the same-sex parent's demise. The final resolution of this conflict permits individuals to establish a new internal structure, including a capacity to regulate desire and guilt. While working with soldiers returning from World War I, social workers found that Freudian theory was consonant with casework practice (Danto, 2009). However, a debate soon arose between the diagnostic school, which relied on Freudian theory with an emphasis on the unconscious, and the functional school, which stressed Otto Rank's ideas about the conscious will (Goldstein, 2002).

Conceptions of Mind in Ego Psychology

While early psychoanalysts gave weight to the drives, American theorists placed emphasis on having a strong ego that could cope with reality, impulses, and feelings. The id, the ego, and the superego were the three intrapsychic agencies in Freud's structural theory. In this model, the id is thought to be composed of aggressive or sexual wishes; the ego is considered the mediator between the id and the outside world, and the superego is, in effect, the individual's conscience. By calling upon a range of defense mechanisms, ego psychology proposes that the development of a strong ego helps individuals deal with conflicts. These ideas became the foundation for social work practice approaches such as the problem-solving model (Perlman, 1957).

Conceptions of Mind in Object Relations Theories

There are a number of theorists subsumed under the heading of object relations. The term object relations can refer to one's relationships with other individuals, to the internal mental representations of others, or to an internal image of oneself. The theory encompasses the idea that instead of being

motivated by their drives, individuals need to connect with others. More specifically, theorists propose that each individual bears the traces of early relationships, and that these internalized representations become part of each individual's relationship patterns. Though not generally credited, social work's early emphasis on the therapeutic relationship may be regarded as a forerunner of object relations theories' stress on the transference (a reflexive, unconscious repetition or revivification of varying combinations and patterns of ideas, fantasies, affects, attitudes, or behavior, originally experienced in relation to a significant figure from one's childhood past, that have been displaced onto an intercurrent interpersonal relationship).

In describing human development, the object relations school emphasizes how caregivers and infants attach and individuate (Bowlby, 1988), as well as how attachment influences brain development (Malekpour, 2007). Members of the women's movement were critical of the attachment theory's emphasis on the role of mothers, while minimizing the role of fathers (Hollway, 2006). Social workers were also critical, and thought material needs such as food and clothing were more crucial (Brandell and Ringel, 2007).

Conceptions of Mind in Self Psychology

Heinz Kohut, who founded self psychology (a treatment orientation within psychoanalysis that encourages the growth of an integrated and cohesive intrapsychic structure through empathic attunement and the internalization of particular functions initially proffered by the therapist), believed that a cohesively functioning self could not develop in isolation, but instead that beginning in childhood, individuals required selfobjects (a term devised by Kohut to refer to a particular kind of object relationship in which the object is actually experienced as an extension of the self, without psychological differentiation. According to the theory, there are distinctly different though equally necessary kinds of selfobject experiences: mirroring selfobjects, "who respond to and confirm the child's innate sense of vigor, greatness and perfection"; idealized selfobjects, "to whom the child can look up and with whom he or she can merge as an image of calmness, infallibility, and omnipotence" (Kohut and Wolf, 1978: p. 414); and alter ego or partnering selfobjects, who provide a range of experiences through which children acquire a sense of belonging and of essential alikeness within a community of others). Kohut defines selfobjects as objects experienced as being a part of or an extension of the subject's self. He identified three types of selfobject experiences: mirroring, idealization, and partnering. He thought mirroring selfobjects reflect back a child's greatness, idealizing selfobjects offer a child an infallible caregiver, and partnering selfobjects provide a child with the experience of someone who is like him or a sense of community. Related to the three types of selfobjects is an intrapsychic structure called the tripolar self (the intrapsychic structure linking particular kinds of self/selfobject relationships with corresponding poles of self-experience, constituting the grandiose-exhibitionistic self, the idealized parent imago, and the alter ego). The tripolar self consists of a grandiose exhibitionistic self associated with mirroring, an idealized self taken from experiences with the child's idealized selfobjects, and an alter ego that recognizes the reality that others bear an essential alikeness to the self. Kohut used the term transmuting internalization (the developmental process whereby a function formerly performed by another is taken into the self and becomes the enduring, unique psychological structure of that individual, occurring via optimal frustration and optimal gratification, and characterized by incremental accretion and consolidation) to refer to the gradual assimilation of functions (e.g., soothing) originally associated with the selfobjects. Although best known for his emphasis on the importance of empathetic attunement, Kohut also acknowledges that individuals need nontraumatic disappointments to develop (Kohut and Wolf, 1978). Due to social work's commitment to working with vulnerable populations who can be stymied by disappointments, there is potential for greater use of this framework in the creation of practice models.

Conceptions of Mind in Lacanian Theory

Jacques Lacan (2007) has made contributions not only to psychoanalysis, but also to linguistic and literary theory. His exploration of language involving Otherness, as it relates to race and class, offers psychoanalysts and social workers a point of convergence.

Lacan distinguishes three agencies in the psyche: the imaginary order, the symbolic order, and the Real. The imaginary order is characterized by primitive self-knowledge without language, fantasy, and images that equates with the infant's entry into society. The newborn is unable to distinguish himself from his mother or the Other and sees himself in fragments. Later, at 6–18 months, the infant recognizes his mirror image, his experience of himself as a unified individual separate from the Other. This is the first step toward the creation of the subject and it is the beginning of social interactions that help identify the self in terms of the Other (Sarup, 1993).

The symbolic order or the big Other involves linguistic collaboration characteristic of communities (Zizek, 2006). Lacan believes there is a set of signifiers that are more than words; they embody concepts with meaning that form narratives about the subject and create rules that govern behavior. Language eventually teaches one what to desire, and introduces children to loss. Lacan links desire to the oedipal crisis, which, in turn, leads to the child entering the symbolic stage. During a child's fifth year, when he or she needs to renounce the desire for the mother and suffers defeat in relation to the father, a symbolic castration takes place. There ensues a pact between the child and the parents in the social order that Lacan calls the Name-of-the-Father.

The structure of the Real is one in which the individual is free from all desires and not affected by worldly enticements. The Real resists symbolization but holds truth. It is impossible to attain; indeed, we only have partial access to the Real (e.g., in dreams) (Sarup, 1993). Note that Lacan's 'other' (lower case 'o') refers to a person with whom one has an imaginary relationship (someone similar to oneself) and 'Other' (upper case 'O') refers to a person or institution that serves a symbolic function (someone or something with authority) (Fink, 1997: p. 232).

Conceptions of Mind in Relational and Intersubjective Theories

Relational theorists argue that one develops as a result of one's early relationships with parents and other figures. Recurring relational patterns develop during infancy and childhood, and eventually unconsciously organize emotional and relational experiences, thus offering rules of what to expect in interactions. Both social work and relational theorists seem to emphasize a less hierarchical relationship model, as indicated in social workers' use of the word 'client' (vs 'patient') and in relational theorists' emphasis on the contributions of both therapist and client (Benjamin, 1988).

Psychopathology in Classical Freudian Theory

Freud thought symptoms or compromise formations occur when despite repression there is an inner conflict involving one's sexual and aggressive wishes with the external world. In his psychosexual development theory, Freud asserts that psychopathology occurs when there is a fixation of instincts and early developmental arrests that prevent individuals from being able to move forward in their development.

Psychopathology in Ego Psychology Theory

In ego psychology, psychopathology is directly related to how the ego functions as it mediates between internal forces and external demands. Having inadequate defenses or coping mechanisms lets in unacceptable sexual or aggressive wishes from the unconscious and superego disapproval that stymies growth. Ego functioning is also influenced by constitutional deficits, overstimulation, excess frustration, and defenses that were adaptive in childhood but are problematic in adulthood.

Psychopathology in Object Relations Theories

Object relations theorists propose that disturbances in the mother–infant relationship influence psychic structure formation and how one relates to others. Starting in infancy, problems can occur when the infant does not have a responsive caregiver who can offer him or her an internal representation of a relationship that brings with it a sense of well-being (Waddell, 2002). Object relations theorists are interested in severe psychopathologies and unyielding defenses (Kernberg, 1992). The clinical symptoms that suggest object relational problems include disturbances in an individual's capacity to develop mutually supportive relationships.

Psychopathology in Self Psychology Theory

Kohut essentially understands pathology in terms of selfobject disorders, which occur when there is a failure in cohesion or a fluctuation between feeling inferior and overestimating the self (narcissism). When individuals suffer from traumatic disruptions in ties with mirroring and idealized selfobjects, there is a corresponding failure of transmuting internalization or the taking in of functions (such as self-regulation) necessary for the development of self-cohesiveness. The result may lead to a range of symptoms, referred to as disintegration products, or an experience of anxiety referred to as disintegration anxiety (the fear of breaking up of the (nuclear) self, described by Kohut as the deepest form of anxiety an individual can experience, its origins traceable to the earliest preverbal stages of psychological development).

Psychopathology in Lacanian Theory

For Lacan, psychopathology arises not from conflicts involving ego, id, and superego, but from how an individual deals with truth and being symbolically castrated or dominated by society. Lacan formulated three categories of psychopathology – psychosis, neurosis, and perversion; neurosis is further subdivided into hysteria and obsession (sometimes including phobia). The ability to access the symbolic order (initiation into the Law or the Name-of-the-Father precipitated by the oedipal crisis) in neurosis is what differentiates it from psychosis, in which there is no access to the symbolic order. In other words, in psychosis, the unconscious is present but not functioning. The pervert, unlike the psychotic, is initiated in the symbolic order, but unlike the neurotic, does not fully understand the reasoning behind the Law.

Psychopathology in Relational and Intersubjective Theories

Because relational theories focus on interpersonal patterns, there are no extensive symptom listings that can be used as a diagnosis. In relational theories, problematic repetitive patterns of relating to others can reflect psychopathology. In addition, symptoms occur when a disruption of needs provokes anxiety in significant relationships within the client's life.

Classical Freudian Treatment

Freud's cure includes the undoing of repression, resulting in the freeing of energy and emotions. This undoing of repression makes the unconscious conscious, which eventually leads to the client gaining insight into the meaning of behaviors and symptoms. To facilitate a cure, psychoanalysis makes use of free association, interpretation (called the 'central therapeutic activity' of the psychoanalytic clinician, interpretation represents the clinician's understanding of a client's mental life. Some psychoanalysts link the concept almost exclusively to the psychoanalytic notion of resistance, believing that any interpretative comment made by the clinician should be expressly designed to draw a client's attention to a resistance. Others, however, have defined the term somewhat less narrowly, viewing an interpretation as a statement of new knowledge about a client. Several different basic kinds of interpretation have been described in the dynamic literature. These are genetic interpretations, dynamic interpretations, interpretations of

resistance, and transference interpretations), dream analysis, and the transference.

Ego Psychological Treatment

Clinically speaking, practitioners of ego psychology assist patients in strengthening their egos so that they can better cope with the pressures from their id, superego, and society in general. During treatment, the therapist helps individuals to develop mature defenses, and to use conflict-free adaptations when problems arise. An expansion of the person's capacity to accept unpleasant realities is a sign that ego strength is improving.

Object Relational Treatment

While there are certain conceptual dissimilarities among the various object relations theories, treatment usually focuses on the internalization (refers to those processes that contribute to the development of an internal world (sometimes referred to as the representational world) and to the consolidation of internal structure. Includes incorporation, introjection, and identification) of relationships, particularly the therapeutic relationship. Thus, object relations therapists often work in the transference while they examine the client's internal world. Practitioners with this orientation make interpretations, while monitoring their clients' as well as their own feelings, associations, and fantasies.

Self Psychological Treatment

Self psychological treatment, which is divided into the distinctive treatment phases of understanding and explaining, helps the client to develop missing functions that he or she failed to acquire earlier in life from selfobjects. Therapy is based on providing empathic experiences that might contribute to developing a cohesive self (the essential self-structure of a well-adapted, healthily functioning individual whose self-functioning evinces the harmonious interchange of ambitions, ideals, and talents with the events of everyday life). In addition to providing an attuned experience, working through ruptures helps the client achieve transmuting internalizations (i.e., taking in the therapist's functions, including affect regulation). Interpretations are used to help clients understand their overreaction to injury and explore how to restore cohesiveness after an empathic failure.

Lacanian Treatment

For Lacan, the goal of treatment is not to enhance an individual's well-being but to uncover the truth about the client's desire. Lacanian analysts believe that truths about a client's desire are present in discourse (even if discourse cannot articulate the whole truth about desire) (Qazi, 2011). In Lacanian treatment, the practitioner offers an interpretation that makes the unconscious desire conscious. In doing so, the therapist works with what Lacan calls signifiers (representing the subject) and the master-signifier (representing the subject for all signifiers), which can have traumatic meaning for the subject. Lacan believes therapy can help subjects modify their signifiers or find new signifiers, thus enabling them to reorder their sense of self and of their relations to others. This is achieved through a process called re-signification, which reduces signifiers' traumatic meaning by integrating them into self-understanding.

Relational and Intersubjective Treatments

Relational therapists are noted for emphasizing a collaborative interaction between client and therapist, their mutual construction of meaning in the therapeutic relationship, and their less adherent stance toward technical restrictions. Treatment in relational models delves into the pattern of the client's relationships with the therapist and others, and tries to ameliorate maladaptive patterns so a client can interact with others more securely.

Brief Psychodynamic Treatment

Due to managed care, concern about outcome measures, and a desire to meet their clients' needs, social workers often use brief treatment models. Since traditional psychodynamic therapies that explore relationship patterns often take time, clients with specific goals or limited time and financial resources frequently consider short-term therapy. Among the challenges implicit in brief treatments are the need to establish a working alliance rapidly and to focus on a specific objective that can be achieved within an agreed time. Therapists also find that while having a specific goal creates more structure, it limits free association.

Controversies Involving Freud's Legacy and Contemporary Critiques of Psychoanalytic Thought

Psychoanalytic thought has gradually been expropriated, absorbed, and popularized, pervading both our intellectual life and common culture. Signal psychoanalytic precepts such as dynamic motivation, unconscious fantasies, oedipal desire, separation anxiety, or the notion of intrapsychic conflict and defense have remained as disquietingly powerful in contemporary times as they were for Freud's detractors and adversaries in the last century. One example may serve as an illustration.

Jeffrey Masson (1994) argued that Freud's 'abandonment' of seduction theory was a deliberate, scientifically dishonest move calculated to end his isolation from the Viennese medical establishment due to his revolutionary ideas. Masson's controversial thesis soon led to a contentious debate, waged in the professional journals, as well as the popular media. Intellectual historians (e.g., Peter Gay, 1988) have deemed Masson's thesis 'preposterous' for two reasons. Not only did Freud, in subsequent years, continue to propose equally radical ideas, but he also acknowledged, though painfully, that real seduction and rape were indisputable facts in at least a few cases of which he had direct knowledge.

Various critiques have also been made against psychoanalysis and psychoanalytic thought. Below, we consider carefully five rather specific criticisms of psychoanalytic thinking (Portions of this section are adapted, with permission of the publisher, from Brandell's 2004 book, *Psychodynamic Social Work*.)

Psychoanalysis Is Not Empirically Valid

Opposition to psychoanalytic ideas on the basis that they are conjectural, untested, and unsubstantiated by empirical methods, or in more contemporary patois, not 'evidence based,' has constituted one of the greatest challenges facing psychodynamically oriented practitioners and academicians.

Psychoanalysis, while employing empirical methods, is not an experimental science. Freud, however, was very eager to link his clinical findings with the prevailing quantitative science of his day (Holzman, 1998), associated with scientists such as von Helmholtz, Herbart, Fechner, and Brucke (Sulloway, 1979). Freud's attempts to treat psychoanalytic data as analogous to findings from the biological sciences, as well as his efforts to create a psychological theory modeled after the physical sciences were less than successful (Galatzer-Levy et al., 2000).

Historically speaking, psychoanalytic investigations were, with some notable exceptions, principally not quantitative in nature. These exceptions included a handful of large-scale investigations, such as the Menninger Psychotherapy Research Project, the Boston Psychoanalytic Institute Studies, and Fonagy and Target's (Fonagy and Target, 1994, 1996; Target and Fonagy, 1994) work at the Anna Freud Centre. Much of the current research on psychodynamic and psychoanalytic treatments is summarized by Shedler (2010). There is arguably more research now – not simply employing qualitative but, increasingly, quantitative methodologies – than ever before. However, this body of research is still comparatively small, especially when one considers how extensively cognitive-behavioral therapies have been researched. Some have argued that the relative absence of experimental data in psychoanalytic research, the failure to present psychoanalytic data in an experimentally testable form equivalent, for example, to data derived from other, nondynamic forms of therapy, invalidates it as an empirical discipline.

However, such a stringent definition of empirical science also excludes sciences such as astronomy and geology (Holzman, 1998: p. 5). Regardless, in consequence of this predominantly qualitative, nonexperimental research base, exponents of psychoanalysis have been disadvantaged in an academic community that places disproportionate value on nomothetic research – investigations that search for general laws or traits, and that are consonant with the philosophy of positivism. This disadvantage has been magnified to some extent insofar as the effects of other therapeutic approaches (e.g., cognitive or behavioral treatment) are readily measured and their efficacy supported by quantitative methods. Although there is now greater consensus that the nature of psychoanalytic findings is indisputably empirical, the comparatively small body of evidence supporting claims of the therapeutic efficacy of psychoanalytic and psychodynamic treatments undoubtedly led to a general decline in their status in the 1980s and 1990s, a situation that has only recently captured the attention of psychoanalytic researchers.

Psychoanalysis Is Elitist and Irrelevant

Another common charge leveled at psychoanalysis is that it constitutes an elite form of treatment, an inappropriate and largely irrelevant body of knowledge for social work expressly designed for neurotic female patients, who possessed vast financial resources and were able to commit literally to years of intensive (four to five sessions per week) therapy. For these critics, psychodynamic thought is suspect, because it has the effect of derailing the profession from its historical mission – serving the poor and underprivileged. Perhaps the most prominent critique along these lines was advanced by Specht and Courtney (1997), though this argument has been made many times before and since.

The essential problem with this critique is that it is based on various misconceptions and falsehoods that nevertheless continue to influence social work academe. First, psychoanalysis even as practiced by Freud and his early adherents was never exclusively with a neurotic clientele. Many of Freud's patients might not even be considered neurotic today, but rather suffering from character disturbances, posttraumatic and dissociative disorders, and even psychotic-like problems. Furthermore, treatments averaged under 2 years, and according to well-documented research, Freud had equal numbers of female and male patients, some treated gratis. Even assuming such criticisms are not spurious, reflexively equating the psychoanalysis of Freud's time with the rich spectrum of contemporary psychoanalytic psychologies and treatments is both misleading and misinformed.

Are psychoanalytic theories irrelevant for contemporary social work practice? Continued reliance in social work education on the work of Erik Erikson (psychosexual/psychosocial epigenesis) and John Bowlby (human attachment theory), theorists deeply influenced by psychoanalytic tradition, argues convincingly against this supposition. While such developmental thinking continues to pervade the contemporary social work literature, its theoretical origins in psychoanalysis are often unacknowledged, or even disputed.

The most damaging assertion is that psychoanalysis was designed exclusively for rich people, and is unmindful of the very real problems of the poor, the disenfranchised, and the downtrodden. Once again, this represents an oft-repeated but patently false, revisionist notion of psychoanalytic history (Danto, 2005). Freud's expressions of social conscience, arising during an epoch favoring radical social democratic ideals, led to the creation of cooperative mental health clinics throughout Europe (Danto, 2005: pp. 1–2). These same rich traditions are represented in the work of leading social work authors (e.g., Redl and Wineman, 1951, 1952; Ekstein, 1966; Fraiberg, 1987; more recently, Marans, 2005; Bragin, 2010).

In the United Kingdom and elsewhere, a different, though not unrelated, critique emerging in the 1970s argued against a longer term psychodynamic approach for cases, particularly those under public agency auspices, where little behavioral or other symptomatic improvement could be demonstrated over time. In such instances, psychodynamic treatment was felt to

constitute a waste of scarce resources (L. Dominelli, personal communication, 31 May 2013).

Psychoanalysis Is Antifeminist

In discussing Freud's views of feminine development and female sexuality, it should be acknowledged that Freud, himself, seemed less than fully satisfied with his understanding of women, whose sexual life he once described as a "dark continent for psychology" (1925: p. 212). In that essay, he observes that his findings about female sexuality are only valuable to the degree that they "… turn out to have general validity and to be typical" (p. 258). Later, when he returns to this topic (1933), he cautions readers, "If you want to know more about femininity, enquire from your own experiences of life, or turn to the poets, or wait until science can give you better answers" (p. 135).

A number of psychoanalysts, many of them women, began in the 1920s to challenge Freud's conclusions about the nature of femininity as well as the biological determinism in which these suppositions were rooted. Karen Horney (1939), for example, articulated a model of female development at fundamental variance with Freud's classical schema. Believing that female sexuality represented a 'primal, biological principle,' she hypothesized a basic male envy of the female capacity for reproduction, and disputed Freud's claim that the wish for a baby represented a compromise solution to the girl's inability to acquire a penis. Motherhood, she asserted, represented the psychological bedrock, with a corresponding biological principle, the instinct for procreation.

Horney and others gave increasing emphasis to environmental forces in shaping the personality, and in particular, the course of female development. This body of work came to represent the culturalist tradition in psychoanalysis. Horney's final position on the topic was that femininity, as a product of culture, does not as such exist (Buhle, 1998). What Freud had termed 'feminine masochism' – feelings of inferiority, dependency, indeed neurosis itself – was not an immutable, biological given, but rather culture-specific.

Other feminists, both academicians and psychoanalysts (Sherfey, 1966; Shainess, 1975; Mitchell, 1974; Chodorow, 1978) have made significant contributions to understanding femininity and female psychosexual development. Arguably, the most influential among these is Jean Baker Miller (1976). Baker Miller is credited with launching the self-in-relation model, a radical new paradigm for understanding women's development, emphasizing the original mother–daughter relationship, and relational phenomena such as affiliativeness, nurturance, empathy (vicarious introspection or the feeling of oneself into the experience of another. The capacity for empathy is regarded as a crucial *sine qua non* for healthy development of the self; chronic and sustained lapses or failures in (parental) empathy are believed responsible for various kinds of structural pathology), and compassion. Baker Miller believed that empathy, as a central organizer or structure of the female personality, explained a great deal about both normality and dysfunction in women's lives. While Freud's Oedipus illuminated aspects of male development, advocates of self-in-relation theory, following Horney, argue that an entirely new model is required to understand female development.

Psychoanalysis Pathologizes Clients

The broad appeal of the 'strengths perspective' to contemporary social work has been underscored by its rapid incorporation into not only our practice and scholarly literature, but also our professional lexicon. Emphasizing empowerment, resilience, healing, and wholeness, this perspective is defined by its abiding focus on clients' personal narratives and workers' responses to them. The worker's capacity to listen specifically for the client's strengths in surmounting adversity and misfortune paves the way for 'transformation and growth.' The work is always collaborative, 'possibility' rather than 'problem-focused,' and unburdened by a priori assumptions about limitations imposed on the client by trauma and abuse, handicaps, illness, and other personal struggles.

Although not always named specifically in these discussions, psychoanalysis is implicitly assumed to place undue emphasis on client weaknesses and pathology, and is thus regarded as deficit-based. However, both historical and more contemporary developments argue against the legitimacy of such claims. The first development is the gradual ascendancy of the 'two-person' model in psychoanalytic thought. Indeed, the assumption that psychoanalysts can function as neutral observers, optimizing their position to make systematic interpretations of the client's transference, has been largely discarded. Instead, most contemporary psychodynamic clinicians assume a reciprocal, mutually influential relationship to exist between therapist and client, and further, that such mutuality and intersubjectivity are central to therapeutic progress.

Additionally, there is good reason to question the general assumption that psychoanalysis places undue emphasis on client weaknesses or abnormalities. For example, Heinz Hartmann (1939) long ago proposed a 'conflict-free ego sphere' composed of functions such as attention, concentration, intention, language, recall, and motor development, all of which subserve adaptation. This view influenced others, such as Robert White (1959), who examined concepts such as effectance and competence, and Erik Erikson (1959), the first psychoanalytic researcher to chart the human life cycle. Such contributions highlight normative development and normal intrapsychic mechanisms and structures. In fact, the field of resiliency, which is closely allied with the strengths perspective, is historically associated with several well-known psychoanalytic researchers (e.g., Coles, 1986; Anthony and Cohler, 1987; Lifton, 1993).

Psychoanalysis does place equal importance on psychopathology, but unlike biological psychiatry, attempts to extrapolate dynamic meaning from pathological signs and symptoms, rather than treating them merely in descriptive terms. Is this the equivalent of pathologizing the client? Particularly in light of the contemporary psychoanalytic emphasis on mutuality and reciprocity within the treatment relationship, and the gradual abandonment of the search for 'historical truths' in psychoanalytic treatments, such a critique seems now to lack substance.

Psychoanalysis Does Not Focus on the Environment

Another common charge leveled at psychoanalytic theories and psychodynamic clinicians is that psychoanalysis is not sufficiently sensitized to the client's environmental surround. Using examples principally tied to early classical psychoanalytic formulations, these critics note that Freud devalued the contribution of environment (or 'nurture'), instead positing that endogenous factors claimed far greater importance in healthy and pathological development. Although Freud continued to emphasize the role of constitution in favor of environmental forces in his developmental theory, by 1923, he had assigned a far greater role to object relations.

The contributions of culturalists (Horney, 1939; Fromm-Reichmann,1950; Sullivan, 1953), ego psychologists (Hartmann, 1939; Erikson, 1959), and 'middle traditionalists' (Fairbairn, 1952; Winnicott, 1965) highlight important shifts in the role imputed to the extramural environment. Others (e.g., Spitz, 1965; Mahler, 1968), whose clinical work and research focused on infant–mother interactions and pathology, also figured prominently in evolving psychoanalytic conceptions of environment between the 1940s and the 1960s.

Winnicott was among the first psychoanalytic theorists to devote serious attention to the role of environment. His view, which may have presaged ideas associated with constructivism and intersubjectivity theory, is notable for its designation of a transitional realm of experience linking objective, reality-based experiences to exclusively subjective ones.

Others, too, have shaped the contemporary psychoanalytic perspective on the environment, including John Bowlby (1988), Hans Loewald (1962), Heinz Kohut (1977), Daniel Stern (1985), and Robert Emde (1992). Using systematic observational methods, researchers such as Stern and Emde have approached environmental phenomena in ways that are far less encumbered by theory than, e.g., Mahler's early studies.

More recent psychoanalytic formulations appear to have made progress in elucidating the role of environment in development as well as in the process of treatment, and there is mounting evidence both of greater interest in the person-social environment matrix among many analytic writers as well as a willingness to consider different theoretical positions (e.g., social constructivism) in the quest for improved understanding of environmental phenomena.

Psychoanalysis and Clinical Social Work: a Reappraisal

Much has changed in the psychoanalytic world since Freud's time. Multiple psychoanalytic psychologies, each with its own vision of human development, psychopathology, and the treatment process, now stand alongside of Freud's classical formulations. Challenges to the empirical basis of psychoanalytic treatment and its formulations about development and dysfunction have spawned a new and more promising body of research. The shift from a one-person to a two-person psychology, the gradual ascendancy of relational ideas, interest and sensitivity in the social environment, and the emerging emphasis on neuropsychoanalysis have likewise been momentous developments.

These are among the more significant changes marking the beginning of the second century of psychoanalytic thought. Social work, too, has changed markedly since the earliest attempts to infuse psychoanalytic ideas into clinical theory and practice. Although psychoanalytic ideas once held a revered status in clinical social work, this has been altered, inter alia, by the introduction of newer theories of change, particularly nondynamic approaches, the shifting requirements of the agencies and clients we serve, and an overriding focus on short-term engagement.

The psychoanalysis of today, while preserving important traditions spanning over 100 years, is a far more sophisticated, complex, and scientifically elaborated body of knowledge. Indeed, we believe that these developments argue convincingly for a reappraisal of what contemporary psychoanalytic theory and practice knowledge have to offer the field of clinical social work.

Abstract

This article uses recent literature and research to illuminate knowledge, values, and skills that social workers require to work with refugees, an emergent field of practice. Literature is drawn from books, journal articles, and online resources including relevant national policy documents. A change of tone is discerned in recent literature, in the form of discourse suggesting that refugees have become less deserving of the protection of their human rights. Their encounters with racism and xenophobia are noted. Dilemmas faced by social workers to fulfill their statutory functions while holding true to their professional principles of social justice are discussed.

Introduction

This article focuses on social work with refugees (rather than asylum seekers), using recent literature and research to illuminate the knowledge, values, and skills that social workers require when engaging in this emergent field of practice. The dilemmas faced by social workers to fulfill their statutory functions while holding true to their professional principles of social justice will be discussed.

Social work is operating in an increasingly international and global environment (Chathapuram and Link, 1999; Midgley, 2000; Powell, 2001). This is particularly apparent when working with immigrants, refugees, and asylum seekers. Literature on globalization and social work explicitly links social work practice to issues of citizenship, inclusion, and participation in civil society. Social workers are inevitably called upon to work in this context, either as agents of the state or in the voluntary sector as members of nongovernmental organizations or not-for-profit organizations. In nonstatutory settings, they are more likely to be able to express their professional principles of social justice. The International Federation of Social Workers (IFSW) reminds us that "The issues surrounding refugees are matters of justice and peace. Social workers in the vast majority of countries will be required to address the problems facing refugees in their practice" (IFSW, 2012: p. 1).

Potocky-Tripodi (2002: p. 3) argued that "Social work practice with refugees and immigrants requires specialized knowledge of the unique issues of these populations." Her comprehensive account of best practice in this new and challenging field is consistent with the IFSW position. She systematically explored the many factors, which practitioners need to recognize in the lives of this client group, using an analysis that reflects on the macro-, meso-, and microlevels of social work practice. Good practitioners, she observed, should be informed about human rights and social justice issues as well as international and local law surrounding immigrants and refugees. Nash and Trlin (2004: p. 2), reporting on findings from two postal surveys in New Zealand, found that practitioners need to be informed regarding service delivery systems and to be knowledgeable regarding key areas such as physical health, mental health, family dynamics, cultural diversity, language, education, and economic circumstances. Social workers also need to be culturally competent and have the requisite knowledge and skills to work appropriately with their immigrant and/or refugee clients. These points will be elaborated on throughout this article.

Definitions

People living away from their country of origin do so for a variety of reasons, sometimes voluntary and sometimes involuntary. When describing the latter, terms may be generic, such as involuntary migrant or more specific, from asylum seeker to convention refugee, or refugees with exceptional leave to remain, or even refugees in orbit (Joly et al., 1997) depending on country of origin and host country.

An immigrant is someone who moves in a planned way, from one country to another, in order to settle permanently in the new country. Immigrants know that they may, if they choose, return to their country of origin. This is not the case for refugees.

According to the United Nations 1951 Convention on the Status of Refugees, a refugee is a person who (http://www.unhcr.org/pages/49c3646c125.html 06.08.13):

> Owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country.

Asylum seekers, in contrast to immigrants and refugees, are people who enter a country without legal documents, or whose documents expire once they have arrived and who claim refugee status. An asylum seeker is a person who has asked for protection but has not received a decision on their application to become a refugee, or is waiting for the outcome of an appeal (SCIE, 2010). Asylum seekers have the right under the United Nations High Commissioner for Rights (UNHCR) Convention to seek a fair hearing to decide on their status as a refugee, but until that hearing, they may demand very little from the country they live in. It is essential that social workers should distinguish between the legal status of asylum seekers and refugees when working with migrants, because, in all countries, people will be entitled to different forms of public welfare support, depending on their legal immigration status. For this reason, using legal definitions

correctly is fundamental, and finding out how clients are placed will assist in understanding their help-seeking behavior and aspirations for settlement (Potocky-Tripodi, 2002: p. 13).

Useful information covering the demographics of refugees, asylum seekers, and displaced persons is available on the UNHCR Web site. The refugees of concern to UNHCR are spread around the world, with more than half in Asia and some 20% in Africa. They live in widely varying conditions, from well-established camps and collective centers to makeshift shelters or living in the open. It is estimated that there are about 19.5 million refugees in the world (http://www.unhcr.org/pages/49c3646c1d.html 07.03.13).

This article relates to social work with refugees, and this term is used with care to avoid confusion with social work with asylum seekers (see asylum seekers article) or migrants. Convention refugees are included here, but efforts have been made to refer to them in the context of a postasylum seeker category.

Literature Review, Introduction

Research and publications about refugees and social work have recently increased. As refugees from a variety of countries and ethnicities have faced displacement, trauma, and loss, there are resettlement opportunities for some. Resettlement calls for courage and resilience and may involve unforeseen difficulties such as stigma, unemployment or underemployment, unwelcome climatic change, new languages, strange housing, cultural differences, racism, and perhaps the most important of all, loss of family members.

Literature reviewed in this article is drawn largely from books, journal articles, and online resources such as relevant national policy documents. Journal articles date predominantly from the year 2000 to the present, and the journal *International Social Work* is one of the main resources. Material from the UNHCR Web site has also been helpful. This discussion of research themes and sources is designed to point up consensus and diversity, recognizing the inevitable ethical dilemmas in international social work and the range of practices within the parameters of different welfare states (Dominelli, 2004; Hugman et al., 2010). It begins with a brief historical approach, and records some of the political responses to refugee populations in nation-states which have, over time, developed very different welfare regimes (Sainsbury, 2006).

A change of tone can be discerned in the literature, in the form of a discourse suggesting that asylum seekers and refugees have become somehow less deserving of the protection of their human rights. Instead, they come under suspicion and their encounters with racism and xenophobia are noted in recent research (Masocha and Simpson, 2011; Refugee Council, 2004). The status of social work, its ethical values, and the expectations social workers face as they carry out their work are a particularly challenging context for practice.

Literature Review, Historical and Political Contexts

The 1951 Geneva Convention on the status of refugees defined refugees in relation to events that took place before 1951, which is why, in 1967, a protocol was added to the Convention to include people who were unable or unwilling to return to their country of origin post-1951 (Lacroix, 2006). Lacroix made a helpful observation, which underpins recent thinking about the uneasy relationship between universal human rights and the asylum/refugee responses instituted in individual nation-states. She writes:

> States which have adhered to the Convention have instituted their own refugee regimes, according to their own historical, political, ideological and social relationships to non-citizens. Hence the disparity among refugee determination systems across the western world and conflicting national views on what constitutes a refugee.
> Lacroix, 2006: p. 21

Sainsbury's (2006) comparative analysis of the social rights of immigrants in three countries exemplified three different types of welfare regime. She described the United States as having a liberal welfare regime, with an inclusive immigration policy in which rights are based on need and land of birth (*ius soli*). Germany, she described as having a conservative welfare regime, mediated by an exclusionary immigration policy such that rights are based on work and lineage (*ius sanguinis*). The third welfare category is exemplified by Sweden, with its social democratic welfare regime according to which rights are based on citizenship and residence (*ius domicilii*) (Sainsbury, 2006: p. 231). These three welfare regimes, each with its own criteria for negotiating rights, provide a useful schema for understanding ways in which different nation-states have interpreted universal rights legislation and developed and applied national policies for immigrants, especially asylum seekers and refugees. Both Hugman et al. (2010) and Pirjola (2009) pick up on this analysis to explore its implications for the uneasy fit between international and national human rights discourses. Hugman et al. apply it to the predicament in which social workers now find themselves, noting "the contradiction that lies between the universal rights of all human beings to live lives of dignity and the exclusionary nation-based notions of social citizenship" (Hugman et al., 2010: pp. 637–638).

The professionalization of social work cannot occur in isolation from increasing demands and expectations that social workers and colleagues face in their daily practice (Maidment, 2013). In 2001, the IFSW and International Association of Schools of Social Work jointly defined social work as "… social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work" (IFSW, 2012: p. 1). Qualified social workers are, therefore, expected to know about human rights legislation as it relates to refugees and to understand government policies, which provide the legal context for their practice in this field. They need to be aware of international agreements, conventions, and guiding statements that concern the status of refugees to become competent advocates for them.

Literature Review, Electronic Resources Informing Macro- and Micropractice

It makes sense when researching an article for an electronic encyclopedia, to identify relevant Web sites and electronic resources belonging to a range of agencies and organizations including the United Nations and other international

organizations, with selected statements and conventions on human rights, as well as examples of national legislation, government policies and social work practice standards, and refugee voices.

The IFSW Web site publicizes a range of policy statements for best practice including a standard setting policy statement on refugees (http://ifsw.org/policies/refugees/ retrieved 14.04.13). It emphasizes the need for a holistic approach when working with refugees, caring not simply for material, but also for psychosocial needs. Ethical values underpin this work, imbued with a belief in the intrinsic value of each human being and the rights of the individual to seek asylum and to be treated with respect for their human dignity. "… the social work profession accepts its share of responsibility for responding to the distress of refugees, and strives for the fullest possible involvement of refugees themselves in meeting their needs" (http://ifsw.org/policies/refugees/ retrieved 14.04.13: p. 1). Key areas of knowledge are outlined and a measure of the success of intervention is seen to be the provision of 'durable solutions' to the problems faced by refugees, together with "the achievement of self-sufficiency, economic independence, spiritual and intellectual fulfillment" (http://ifsw.org/policies/refugees/ retrieved 14.04.13: p. 1). The IFSW explicitly supports the work of the United Nations and believes in the value of working in partnership with other NGO organizations to lobby for social and political changes in this field.

The Office of the UNHCR was established on 14 December 1950 by the United Nations General Assembly. The agency is mandated to lead and coordinate international action to protect refugees and resolve refugee problems worldwide. Its primary purpose is to safeguard the rights and well-being of refugees (www.unhcr.org/). The site links directly to the Geneva Convention 1951, and includes a brief history of the UNHCR and describes the main areas of work it undertakes. The 'Figures at a glance' page is particularly helpful.

Human rights legislation is a fundamental resource for social workers when advocating for their clients. In the context of refugee work, as argued by Hugman et al. (2010), it provides a powerful and essential counterbalance to national or regional legislation and policies, which would seek to exclude or marginalize asylum seekers and refugees. In addition to the obvious sections on human rights, this site has good links to other topics including an interesting and innovative link to the UN Cyberschoolbus with its interactive declaration of human rights and moving stories by children whose rights have been abused (http://www.un.org/cyberschoolbus/humanrights/index.asp). Easily navigated, the Cyberschoolbus is definitely worth boarding and links one to the Declaration of the Rights of the Child and another to the Universal Declaration of Human Rights.

Two national organizations featured in this article are concerned either to set standards for good social work practice, or to see that social workers have resources for achieving the standards expected of them when working with refugees. The (American) Council on Social Work Education (CSWE) makes a pertinent, but generic statement that social workers

- understand the forms and mechanisms of oppression and discrimination;
- advocate for human rights and social and economic justice; and
- engage in practices that advance social and economic justice.

(CSWE Educational Policy and Accreditation standards, Educational Policy 2.1.5 www.cswe.org/). There is no direct mention of refugees as such here, but the standard is clearly relevant.

The (English) Social Care Institute for Excellence features a comprehensive guide to good practice with refugees and asylum seekers based on an extensive review of British research publications and a practice survey. Good practice occurs in a context of respect for the strengths and resilience of refugees and asylum seekers. Emphasizing the importance of good information and advocacy skills, this report is a very helpful resource for practitioners (SCIE, 2010).

Finally, a research project featuring dialogues with women refugees in Finland offers a politically aware, gendered analysis, with practical recommendations for ways of working with refugee women (Pittaway and Van Genderen Stort, 2011). The women participants' strongest message was that service provision aimed at assisting refugee integration has to be grounded in a deep understanding of the impact of these experiences on their lives. Many of the women commented that racist and xenophobic behavior and language served to keep the horror of these experiences alive (Pittaway and Van Genderen Stort, 2011: section 1, p. 7). This report models excellent and innovative research methods, provides many links to other research together with a set of excellent recommendations for social workers in this field.

The international human rights and social work agencies and organizations provide a global setting for principled social work practice with refugees. The few chosen to feature here have offered a range of information and links featuring practice standards, research, and a gendered approach which, in this field, is essential. The next section looks at core concepts and theoretical frameworks for practice.

Core Theories and Concepts

A number of theoretical frameworks and models exist to support the kinds of analysis that social workers will find useful when working in this field. Kunz (1981: pp. 49–51) categorized three types of refugee according to their reasons for leaving their countries of origin, reasons which he predicted would affect their resettlement experiences. The three different groups he recognized are 'majority-identified' refugees who identify with their homeland but not with its government; 'events-alienated' refugees, often religious or racial minorities who rarely entertain the hope of returning home; and 'self-alienated' refugees, who for various reasons no longer wish to identify with their nation.

George (2002) categorized models of settlement service delivery as theory based and practice based. Theory-based models include models of cultural competence, antiracist models, ecological models, and empowerment approaches. Practice-based models focus on the different stages or phases of immigrant settlement and adaptation.

Perhaps the most used theory-based model is the ecological model, which social workers are familiar with in many contexts. It ensures that the practitioner takes a holistic approach to their interventions, contextualizing refugees in international and national settings. The importance of a macrolevel analysis for working with refugees was eloquently

expressed by a respondent in a New Zealand research project who commented that:

> You have got to be able to have a structural analysis, you have got to be able to have a global analysis, you have to have political reasons … Because in this sector…if you only have case work skills, you only have … a micro-base approach to your work, it is not going to work, it will be very soul destroying.
> Nash et al., 2006: p. 350

Also within George's theory-based category, empowerment approaches can build on strengths-based practice (Saleebey, 2006) as well as on the social justice principles of solidarity and subsidiarity. Valtonen described social work in Finland as developing a new field of practice, which involves indirect social work and provides a 'pivotal link' (2001: p. 959) as social workers use their expertise to liaise skillfully between the clients' world, bureaucracies, and local community groups. Her study emphasized professional social work responsibilities for humanitarian and social justice work in this domain and identified key skills for social workers – in particular, cross-cultural skills.

George's (2002) second category of models of settlement service delivery, the practice-based model, promotes an understanding of the stages of migration and points up the challenges refugees have endured to arrive at a particular point. If social workers are to work successfully with them to facilitate settlement into a new country, this is also something they need to be aware of. George cited Cox's (1985, 1987) example of the stages approach involving premovement, transition, settlement, and integration, as well as a continuum model in which newcomers move from acclimatization, followed by adaptation and leading to integration (George and Fuller-Thomson, 1997). The stages approach has been taken up by social workers as a useful framework, which emphasizes matters of significance to the people they work with. Practice-based models also distinguish between services run by ethnic communities for their own people and services run by mainstream agencies for newcomers (George, 2002).

These frameworks are helpful in that they identify and clarify a variety of complex variables involved in settlement work with refugees. Many of the issues which these models and frameworks are designed to address are reflected in subsequent research by Nash and Trlin (2004) and Ager and Strang (2004). The latter developed an evaluation tool, 'Indicators of Integration,' based on research funded by the Home Office to develop a framework that would, without being prescriptive, facilitate the planning and evaluation of local projects designed to assist refugee settlement.

From the research, a framework for the indicators is structured into 10 domains, which represent the key factors involved in the process of integration work with refugees. These domains are categorized under four headings and within each domain there are further indicators that provide criteria for assessing integration pertaining to that particular domain (Ager and Strang, 2004: p. 5). The framework, while informed by research findings, is also intuitively perceptive for anyone who has worked in this field.

The four headings are as follows: The first, 'means and markers,' which refer to the four domains that are essential for settlement leading to integration. These are housing, employment, education, and health. These domains are self-explanatory, and without achievement within each of them, refugees cannot be said to have settled into their new community. The second heading is 'social connections' and it refers to social bonds, social bridges, and social links. These links are reminiscent of the ecological framework; in that, social bonds are the connections within a specific (microlevel) community, ethnic, religious, or other, while social bridges are the connections made with the members of external and different types of communities (mesolevel). Social links are (macrolevel) connections made with institutions at local or national levels and include state services. The social domains link well to the work of Valtonen (2001) referred to above.

The third heading 'facilitators' includes two domains, which again are predictably identified as 'language and cultural knowledge' and 'safety and stability.' Again, these domains are self-explanatory. The fourth heading 'foundation' as indicated by its name is a particularly important one, and contains a single domain, which is 'rights and citizenship.' The authors have included helpful examples of how the domains can be used at practice and policy levels, making them user-friendly for the busy practitioner or policy-maker.

This carefully structured framework can be used when presenting research into social work roles and practices. The author has found that recurring themes emerge from research into social work with refugees across time and place. Findings consistently indicate that refugees experience similar needs and requirements and that practitioners describe comparable levels of knowledge, resources, and interventions in approaching their work.

Social Work Roles and Practices

For example, George (2002) reported on research carried out in Canada to develop an appropriate model for settlement services designed to meet the needs identified by the service users themselves, as well as by social workers. She identified "full and equal participation of newcomers in Canadian society" (George, 2002: p. 468) as the aim of the Canadian Council for Refugees. As mentioned earlier, participation continues to rank high on the list of essential components of a successful settlement strategy. George (2002) distinguished two ways in which one can view settlement: first, as a two-way process in which both newcomers and the host society have to adapt to one another; and second, as the provision of settlement services, which can be seen as a duty based on human rights (George, 2002: p. 468). This fits well with Ager and Strang's (2004) 'rights and citizenship' domain and accords with the work of Lacroix (2006: p. 22), when she observes that "How we start linking the international context to local experiences is of particular concern for the social justice side of social work."

George (2002) noted that the Canadian Council for Refugees identified values such as inclusivity, empowerment, respect for newcomers, cultural sensitivity, collaboration, and reliability of services as important in resettlement work. These values reflect those expressed in the United Nations Summit for Social

Development – Ten Commitments (cited by Healy, 2001: p. 288). They are values that every refugee recognizes as essential for their well-being and dignity. A later research project, sponsored by the UNHCR and the University of New South Wales, Centre for Refugee Research, Australia (mentioned above), used a participatory approach to collect the stories and opinions of women refugees in Finland, concerning the stages of their lives as refugees. The research team set out to produce a model for government and civil society to use when working with refugees toward their settlement, with particular emphasis on women and children. The women "consistently recommended that they be involved in solution identification and implementation, and that their previous expertise and knowledge be utilized to assist their own communities" (Pittaway and Van Genderen Stort, 2011: p. 11).

This very useful research project has good detail and stresses some psychological needs for recognition by host workers and society, of traumas and hardships undergone before arrival in host country. Ten global core protection areas proposed by the UNHCR Gender Unit have been identified by UNHCR research using the Regional Dialogues method in India, Colombia, Jordan, Uganda, Zambia, and Thailand. Finland adds an industrial nation-state to the mix. In this set of dialogues, the women talked particularly of their experiences of seeking asylum and settling into Finland. The report compares the global core protection issues and those for Finland and shows a close comparison between them

Global protection issues	*Finnish protection issues*
Individual documentation	Individual documentation
Women's representation in leadership	Women in leadership positions
Sexual and gender-based violence	Sexual and gender-based violence
Shelter	Housing
Sanitary materials	Reception conditions
Health issues	Health issues
Legal remedies	Access to justice
Education	Education
Economic self-reliance	Economic self-reliance
General violence	Racism and xenophobia

Section 1.5, p. 9.

Particular issues of concern arising from the research were:

Language
Employment
Racism, xenophobia in host country
Increased domestic violence and reasons for this
Length of asylum application procedures
Lack of access to counseling to enable them to process the traumas they have experienced.

Section 1.6, p. 10 of 48.

They stressed also the importance of better policies for family reunification. Again, one notes the same themes coming through as from other research.

A small, supplementary selection of authors whose research is particularly relevant to social work intervention in this field includes Weaver and Burns (2001) on understanding the traumatic experiences faced by refugees and asylum seekers; Nash and Trlin (2004) who explored the experiences of generic social workers and NGO workers involved in settlement work with clients who were refugees or migrants in New Zealand; Hagelund, and Kavli (2009) on the importance of employment for refugees when they begin the arduous process of settlement in a new country; Al-Qdah and Lacroix (2011) on Iraqi refugees in Jordan with useful practical ideas; Kreitzer (2002) on the participation and planning of refugee camp programs by Liberian refugee women; and finally, not to leave out the significant but often neglected area of religion, Benson et al. (2012) have researched a study of newly resettled Hindu Bhutanese refugees in the United States.

Ethical Challenges

There remains one challenging matter, raised forcefully by Hugman et al. (2010) and Humphries (2004) who, in different ways, remind social workers of the dilemmas they face in upholding their professional ideals when working in this field. Humphries (2004: p. 93) argues that in relation to implementing immigration policy, "There is no clearer an example of the transformation of social work from a concern with welfare to a position of authoritarianism than in this field, paralleling a more general change in the profession towards a culture of blame and enforcement." In the context of international social work, Hugman et al. (2010: p. 633) ask: "Are social workers engaged in international social work exerting effective political pressure (within their own nation-states) behind their desire for a more equitable global society?" or "is a borderless social work likely to be egalitarian or another nightmare of (inappropriately) universalizing language?" Social workers engaged in settlement programs cannot avoid these questions, for they will inexorably be involved in advocacy, in family reunification issues, leading to international social work with refugees and asylum seekers.

Concluding Remarks

This article offers a necessarily brief guide to the terrain of social work with refugees. It began with defining terms, as a preliminary to looking at international conventions, and statements by human rights and global social work organizations. These are referenced using accessible Web sites, to enable readers to deepen their knowledge of the histories, politics, and values that inform the refugee world. With this foundation material, the author has used a macro-, meso-, microframework to organize a presentation of useful theoretical material at each of these levels, material which practitioners need to be aware of when working with refugees. Finally, research into aspects of refugee settlement in diverse countries has provided a selection of examples of social work practice and refugee experience.

Above all, this article is intended to provoke curiosity and to raise some of the ethical and professional issues that make social work so interesting.

Social Work Education

Malcolm Payne, Manchester Metropolitan University, Sutton, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Social work education prepares people to practice as social workers, and also a social institution incorporating university and social agency interests. It creates practitioners' professional identities, bringing together academic learning with practice and life experience. Distinctive models of social work education exist in English-speaking, European and resource-poor countries. Attempts to create global standards for curricula and organization of social work education are contested. Practice experience in social agencies uses supervision linking administrative checking of actions, education, and personal support. Practice experience generates tensions between universities and social agencies about social work educations' aims.

Social Work Education and Social Work Identity

Social work education is the process of preparing people to practice as social workers, and developing their capacity to practice through learning and personal development. This process starts prior to professional qualification and continues during qualifying education and through lifelong professional development. Educational processes, therefore, help to create the professional and personal identities of social work practitioners.

As with all professional education, social work education also contributes to the formation of the identity of the profession, by its education curricula and the learning processes that are used. By virtue of their shared involvement, the personnel engaged in social work education in universities and in social agencies also develop a shared social identity, which constitutes an identifiable grouping within the social work profession. Thus, 'social work education,' the process, interacts with 'social work education,' the social institution, and both contribute to the identity of social work and contribute to social policy-making, higher education and social agencies.

University and Social Agency Contributions

Social work education is usually provided in universities or institutions providing education at a higher education level; 'universities' in this article includes other higher education institutions. Social work qualifications, therefore, lead to a degree-level qualification and in some countries, is also or mainly available at masters level.

Like other education for professions involved in helping human beings, social work education incorporates contributions from personnel in both educational institutions and social agencies. This is for three reasons. First, many people enter social work having been informal caregivers in domestic settings or paraprofessional or volunteer workers in social agencies, so their early experience as helpers or in agencies forms the basis of all later education. Low-skilled or volunteer jobs with little or no formal training is not regarded as social work, but is variously called paraprofessional work, social care practice, or more broadly 'care work' (Boddy et al., 2006). Paid caregivers employed by individuals as 'personal assistants' are a recent innovation because of 'cash for care' policies in many countries (Ungerson, 1999; Leece and Peace, 2010). Such policies provide grant aid for people to employ their own assistance, rather than staff employed by social agencies organizing services in people's own homes. If such staff or volunteers then decide to seek qualification as social workers, their experience and initial training contributes to the process of qualifying and postqualification social work education that they participate in, and may constrain or enhance social work education accordingly.

The second reason why social work education incorporates input from outside educational institutions is that most social work education includes work experience in social agencies. This generates continuing relationships between educational institutions and social agencies and creates a group of personnel concerned with such 'practice education' or 'practice teaching' or 'field education' or 'student supervision' – the designation of this part of social work education varies in different countries. These educational experiences, the specialized personnel involved, and the links between social agencies and educational institutions through which they are organized produce struggles for influence over curricula and learning processes and over policy-making about the balance of academic and social agencies.

The third reason for the links between educational institutions and social agencies is that, once qualified, practitioners continue in a process of personal professional development and lifelong education that sometimes involves engagement with educational institutions. Many universities and other educational institutions provide advanced postqualifying and doctoral education in social work as part of that engagement (Laot, 2001; Scourfield and Maxwell, 2008).

Models of Social Work Education

A number of models of social work education exist, and while there is increasing international mobility in the workforce, little research exists to understand differences (Spolander et al., 2011). Different forms of social work exist and while most social workers have some education in all, many countries emphasize one or permit specialization. The most widespread practice in developed countries is practical and psychological

help provided through interpersonal relationships with individuals and families, usually called casework until the 1970s; this is what most people understand by 'social work' practice. Groupwork is a development of this, bringing together individuals to meet in small groups, typically of between six and twelve. Groups may focus on changing behavior or bring together people with similar social difficulties to help and support each other, or engage in activities that have educational or personal development objectives (Papell and Rothman, 1966). Groupwork is also important in residential care, where people who are unable for various reasons to care for themselves live in communal settings. Community work involves helping people come together to identify issues of concern and take action to resolve them. This is increasingly called 'macro practice,' since it deals with larger populations than individual, family, or groupwork practice (Payne, 2014). In European countries, there is also an important distinction between social pedagogy or social education, and social work or social assistance (Boddy and Statham, 2009). Social pedagogy has a conception of social work as a positive educational process for individuals and groups with shared interests. It thus avoids the potentially stigmatizing connotations of Anglo-American social work traditions that see social work as a process for resolving problems and most clients of social workers as being socially excluded. An important source of social pedagogy is a group of German philosophers who aimed to develop those social aspects of education that particularly focus on poor people in societies (Lorenz, 1994: 91–97). Social pedagogy is used particularly with children in residential and day care and in community work in which individual and collective self-development and education interact.

Social development is the main form of social work in resource-poor countries where economic development is an important national priority and seeks to incorporate social progress alongside it. African, Asian, and Latin American social work education often contains a strong and sometimes overriding focus on social development (Midgley and Conley, 2010).

History of Social Work Education Structures

Social work education emerged from training courses for employees and volunteers provided by major charitable agencies in the US and European countries in the late-nineteenth and early-twentieth centuries. The charity organization societies operating in large cities at that time favored developing investigatory skills and appropriate moral attitudes among suitable middle-class women through supervision in the field. However, concerns about the quality of charity workers and a wish to claim expertise through establishing a scientific basis for casework methods and underlying political policies opposed to Fabian ideas of social reform led to the establishment of more academic courses (Jones, 1976). These built links with local universities and higher education institutes. The first courses were established in Amsterdam, London, New York, and Chicago in the period 1895–1910 (Kendall, 2000). During or after the first world war, as social work increasingly became a paid occupation, national associations of schools of social work, and international association of schools of social work (IASSW) emerged at the international social work fortnight in Paris in 1928 (Kendall, 1978). Such initiatives were extended to Australia, Canada, India, and a few French- and English-speaking African and Asian colonies over the next 10 years.

After the establishment of European welfare states following the Second World War, and the development of casework techniques, particularly in the US, social work education expanded both in universities and in specialized higher education institutions focusing on professional education in some countries. A network of universities and colleges in Africa, Asia, and South America began to develop courses similar to those in Europe and the US until the 1960s. This was also associated with the expansion of university social science teaching during that decade. There was continued differentiation as social work education in the developing world placed a greater emphasis on social development. These extensions of social work education were encouraged by the US Fulbright Fellowships, Canadian technical assistance, the Catholic International Union for Social Service, and United Nations' initiatives in family planning and eventually in community development (Younghusband, 1963).

Countries dominated by communist regimes de-emphasized the importance of social work in the period 1950–90, favoring instead social programs such as extensive day care and nursery provision for children and support for unemployed, sick, disabled, and retired people through workplace or trade union social support (Simpura, 1995). From the 1990s onward, former Soviet countries, Eastern and Central European countries, and China all developed extensive networks of social work education as a way of promoting social liberalization, improvements in large oppressive residential care institutions providing for people with mental illnesses and intellectual and physical disabilities and in training undereducated workforces hitherto employed in public welfare services (Payne, 2005: 227–241).

Global Standards for Curricula: Internationalist and Hegemonic Views

The interpretation of these developments is contested (Payne, 2005). The internationalist view (Kendall, 1978) proposes that there has been one stream of progress in the development of the profession and its education, based on a universal social science, leading to a coherent paradigm of social work that is relevant everywhere but adapted to fit particular national systems of welfare. This view is reinforced by the way in which former communist regimes adopted Western patterns of social work education in the 1990s. However, alternative views (Payne, 2005; Payne and Askeland, 2008) propose that the internationalist view is hegemonic, with the dominance of Western and particularly American cultural values and professional assumptions leading to the inappropriate importation of models of practice on the unproven assumption that these are universal. This has been a particular issue in relation to the transfer of American models of casework in resource-poor countries (Midgley, 1981), when social development practice was more relevant. In the hegemonic view, different national welfare regimes draw on local cultural and social philosophies, incorporating elements of models of practice in use in other

countries as these become available. There is evidence that this took place in the development of social work in the late nineteenth century, for example, in Japan, and in the differentiation of social work theory and education in the latter part of the twentieth century (Payne, 2005). The dominance of Western models often reflects colonial and postcolonial relationships between Western and resource-poor nations. The hegemonic view argues for understanding of the different cultural and service histories that inform local practice and for facilitating cultural translation between different national practices (Payne and Askeland, 2008).

A recent iteration of this debate has arisen in relation to the development of global standards of social work education, during the first decade of the twenty-first century, as international bodies in social work have sought to develop agreed standards (Sewpaul and Jones, 2005; Gray and Webb, 2008) and as communist and former Soviet countries have developed social work services.

The main area of debate is about Western cultural influence on the curriculum of social work courses, as against the assumed universality of research knowledge. Responding to concern about this issue, the global standards (International Federation of Social Workers, 2012) permit wide variation, allowing different national and cultural traditions to influence the curriculum in each country. The Standards propose that curricula should cover four main areas:

- the domain of the social work profession, for example, social structure and oppression, human behavior and development and the social environment, social work's origins and purposes, social welfare policies;
- the domain of the social work professional, for example, the development of the self-reflective practitioner, the interaction of personal values, and life experience and practice;
- methods of social work practice, for example, assessment, relationship-building and helping processes, social work values and ethics, research methods;
- the paradigm of the social work profession, for example, the dignity and worth of all human beings, capacity-building and empowerment, advocacy, building strengths, respect for diversity.

National curriculum statements cover similar ground in different ways.

The Social Work Education Process

Transformations in Identity

Professional education is a process through which an individual's personal identity is transformed so that it incorporates a professional identity as a social worker. Most elements of the global standards are less contested than the curriculum because they are focused on this process demonstrating a clear commitment to social work values, appropriate selection and learning processes, and fair assessment.

Three elements of the process move in parallel during a practitioner's career:

- practice experience,
- life experience, and
- academic learning.

Each social worker brings together these three elements to create a unique personal identity as a social work practitioner, with links to an academic and professional identity. Post-qualifying education often initiates or supports a practitioner in developing specialist emphases in their work, that further advances the formation of their personal academic and professional identities.

Each transformation in identity includes academic learning and the development of professional skills and values, but personal identity gained through life experience is crucial in social work education, prior to, during, and after any formal educational experience. This is because a social work practitioner incorporates their 'self,' for example, the experience that derives from their gender or ethnicity, as an aspect of their practice (Urdang, 2012). Practice involves modeling behavior and attitudes, using the practitioner's self in a relationship with clients with whom they work. The relationship enables them to influence people who may be excluded from or reject social relationships, and research confirms the importance of honesty and genuineness in relationships between practitioners and clients (Carkhuff and Berenson, 1977) to enable this influence to succeed. Therefore, social workers must be genuinely engaged with the interests of their clients, and their self must be developed to achieve this.

Life and Practice Experience

The importance of the preprofessional personal identity in the formation of a practitioner's professional identity means that even where it is not a formal requirement of entry, many applicants for admission to qualifying social work education find that personal life experiences or work experience motivate them to work and receive training in this field. Therefore, they bring into the education process experience of how people live and how social work is organized and practiced. Because students bring life or practice experience to, the education process requires social work education to use modes of adult learning (Knowles, 1984) that allow students to reflect on and incorporate this experience into the education process. This means that social work education is often problem based and collaborative rather than didactic, and also emphasizes equality, seeing teachers and learners and exploring knowledge and practice together. An experiment on a UK qualifying course developed 'enquiry and action learning' (Burgess, 1992), for example. It used a curriculum based on scenarios and problems encountered in practice, rather than on academic subjects, aiming to integrate academic teaching and practice learning, to build on the knowledge and skills students brought to the course, and to help them become self-directed lifelong learners, able to adapt to the changing demands that will be placed on them as professionals.

The importance of life experience in social work education also leads to a culture in which the personal suitability of applicants for admission to a course and of students during the course is an aspect of the assessment, which may lead to students being failed or excluded for personal rather than professional reasons.

Academic Learning

Academic learning in social work education draws on a wide range of research and scholarship. Pawson et al.'s (2003)

systematic review identifies five sources of knowledge, as follows:

- organizational knowledge,
- practitioner knowledge,
- policy community knowledge,
- research community knowledge, and
- user and caregiver knowledge.

This research indicates that conventional academic knowledge, based on journal and book publication, is not the only kind of knowledge that needs to be incorporated into social work education.

Moriarty's (2011) systematic literature review for the English Department of Health summarizes the available research, and cites available studies, including relevant international research.

- The social sciences, in particular, psychology, sociology, and social policy – although a background in economics and political science also offers contextual understanding for implementing social science in practice. Organizational and management studies also play a part in understanding the social context in which social workers practice.
- Law includes law that governs the responsibilities and legal powers of social workers and law in which they might have to advise clients, such as social security, housing, and other legal rights.
- Practice skills deriving from the social work literature and from micro-psychology, include the main elements of any practice, involving assessing clients, planning appropriate action, intervening in social situations to help them, and monitoring and evaluating the outcomes of the intervention. It also includes skills in interpersonal communication and influence in working with clients and colleagues, also drawing on micro-psychology.
- Cognate professional fields offer understanding that may be transferred to social work from medicine, nursing, teaching, psychology, and skills in interprofessional and partnership working.
- Ethics and values teaching draws on cognate professional literature, including medical ethics, and on philosophy.
- Research appreciation and research methods teaching appropriate to the level of the course sufficient to enable practitioners to understand and critically evaluate research relevant to their practice. This teaching also contributes to practitioner's ability to critically evaluate their practice either through personal research or by participating competently in agency and government quality assurance and evaluation research.
- Critical thinking and critical reflection skills enable practitioners to continue to be self-critical throughout their career (Fook and Gardner, 2007).

Academic learning in social work calls upon the full range of teaching methods commonplace in higher education, including lectures, seminars, and group discussions, together with individual and joint project work. At higher levels of education, this includes research projects, which may also have an integrative function. Practice skills are sometimes taught through skills laboratories, often assisted by video. These involve role-play scenarios to test out student skills and receive feedback, which aims to develop their competence. Agency staff, service users, and caregivers may also be involved in providing feedback to students on their performance in similar situations (Moriarty, 2011).

Practice and Field Education and Supervision

Moriarty (2011) documents a debate, however, about the effectiveness of laboratory teaching of interpersonal skills as compared with practice experience as a learning experience in social agency or field settings. There is a long history of research that suggests that social work students regard practice learning provided in agencies as the most important, enjoyable, or memorable element of their learning. Practice or field education enables students to observe the work of agencies and carry out research or organizational studies (Payne, 2004). It may also provide an important opportunity for international exchange (Payne and Askeland, 2008; Noble and Hendrickson, 2011).

In the Anglo-American model of social work education, a university typically (Bogo, 2010) organizes placements for its students in social agencies for substantial periods, sometimes amounting to half the course program. The most common arrangement is for an individual student to work in the agency, carrying out the same tasks as employees, and supervised by a social worker employed by the agency in doing so. A university staff member liaises with the agency supervisor. This experience allows students to apply and practice knowledge gained in the university setting, and gain experience in transferring academic knowledge to practice settings, and the supervisor assists them in doing so, eventually assessing their competence in practice. Other employees of the agency contribute to helping and assessing the student and provide experience in cooperating with colleagues. While the students undertake a full range of work, they do not carry a full workload, to facilitate the learning process.

Social work supervision, as it is provided both to practitioners and also to students, is a distinctive process containing three elements:

- Administration, checking that the social worker performs professional functions as required by the profession and the agency.
- Education, teaching the social worker knowledge, skills, practical techniques, and appropriate value orientations.
- Support, enabling the social worker to manage their personal reactions to their experiences in professional social work (Kadushin and Harkness, 2002).

This last element is necessary because experience of distressing circumstances, for example, events such as child abuse or bereavement, may be stressful and raise echoes of a practitioner's own life experience in ways that might adversely affect their capacity to function as a social worker or their judgment. Such supervision continues throughout a social worker's career, and experiencing it as part of social work education is an important socialization into the way in which practice is managed within the profession. The support and education elements are organized in an unusual way, compared with supervision in many health care professions, where they are often provided by a consultant independent of the practitioner's

employment. In social work, by contrast, it is typical for it to be provided by their manager. The student social work supervision arrangement mimics this professional convention (Carpenter et al., 2012; Hawkins and Shohet, 2012).

Practice or field education leads to an assessment of the student's competence to practice, again mimicking the social work professional convention that supervision is management as well as education and support. Professional qualification usually requires successful completion of both this element of the course and also the academic program. While there is evidence that the involvement of field or practice educators increases the rage of skills and experience available to social work courses, research also suggests that some find it difficult to fail students in this element of the course (Moriarty, 2011).

The engagement of agencies in field and practice education makes the organization of placements and supervision a site of tension over the influence of field agencies on the curriculum and assessment of social work education. Most of this disagreement reflects uncertainty about the objective of qualifying education (Moriarty, 2011). The areas of disagreement lie in the wish of agency managements for graduates of social work qualifying education to have a high degree of procedural knowledge, ability to assess risk in difficult situations, and decide on appropriate interventions, as against the view of universities that a broader curriculum with transferable skills that practitioners can then build upon in their early practice experience is a more appropriate objective of qualifying education.

As a result of this tension about aims, the position of field or practice educators as part of social education can be ambivalent. They may lean toward loyalty toward the employer conception of social work education or to their position within social work education. The employer view is often represented on behalf of employers or mediated by staff involved in the management and delivery of training, including the organization of field or practice education and student supervision. A related area of difficulty is the internationally increasing use of competence frameworks in practice assessment. These measure outcomes of professional education, in place of guidance on the curriculum to be provided in the teaching of (that is, input to) courses and offer a detailed statement of what students are able to do, tested in a work setting. This emphasis on detailed specification and on outcomes is an implementation of managerialist approaches in New Public Management (NPM), a new settlement in the 1980s of relationships between the citizen and the State and between management, political control and professional responsibilities (Clarke and Newman, 1997). It arose from the neoliberal analysis that comprehensive welfare states on the European social model were not economically sustainable. Consequently, new forms of management were required to control the tendency to extend the coverage of the state and to manage professional activities so that they were more financially efficient, in particular, using quantitative techniques, such as work study (Pollitt, 1993). NPM has a view of management as a generic expertise in which management has its own knowledge base and skills. The debate about competence-based education focuses on how social work education may be developed to be strongly applicable in the context of agency definitions of the aims and content of social work. There has been a greater trend to managerial control by the center, rather than discretion to a local professional service, greater use of legal and procedural processes rather than professional discretion, and greater use of managerialist techniques, such as control by specification of standards, training competences, and performance indicators, rather than permitting the flexibility of discretion. Professional knowledge and skill is subordinated to management and financial control. Work activity becomes deskilled as professional tasks are fragmented. Initially, this is done by codifying and dividing up tasks into smaller components, which practitioners should be able to carry out, called competences.

Competences required as the outcome of education are identified through the functional assessment of what social workers do. These are formalized in occupational standards, which workers should be able to meet, and competences are derived from these which specify workers' performance. Critics of this approach (for example, Dominelli, 1996) claim that organizing social work education through competence testing makes for a mechanistic approach to learning and assessment, which is inadequate for measuring professional knowledge and skills and professional judgment. Also, competence approaches minimize the importance of intellectual understanding and coherent analysis of the field of study; also that they reduce the importance of values within social work. However, competences can be written, and assessments carried out, to include underpinning knowledge and values. Another point is that focusing on knowledge, understanding, and values as a coherent whole makes it difficult for students to apply understanding in practical situations that requires selecting from and using knowledge in less comprehensive packages: competence approaches emphasize education based on practical ways in which the knowledge may be used. Other advantages are that competence frameworks define precisely what a student should be able to do, rather than relying on overall judgments of students' attainment in practice by academic or practice teachers. It also relies on statements about what social workers actually do, rather than theoretical accounts of practice, and is therefore likely to connect rather better with employers' requirements of their workers. Assessment of detailed competences as part of social work education permits a more explicit and defensible statement of practice assessment, but makes it more difficult to see students' attainments as part of their holistic development as practitioners (O'Hagan, 2007).

Lifelong Learning, Critical Reflection and the Learning Organization

Most professions have a process for qualified practitioners to engage in continuing professional development (CPD), a lifelong process in which professionals take responsibility for continuing to develop their skills and knowledge. They do this through reflecting on their work and developing and fulfilling learning objectives that will improve their practice (Megginson and Whitaker, 2007). A basic assumption of CPD is that individual professionals are responsible for and create their own program. Where they are employed professionals, however, the organization in which they work needs to become

a 'learning organization' that facilitates and supports its employees in achieving this (Gould and Baldwin, 2004).

Integral to CPD is that practitioners engage in critical reflection, which puts together three elements of social theory – reflection, reflexivity, and criticality – to describe a way of developing practice skills. Reflection helps professional practitioners plan and do their work with greater understanding of the situations, they are facing and to develop practice theories for professionals. They use the ideas that come out of reflecting on particular incidents to adapt existing theories or create new ones. Reflection is a circular process: you have an experience, reflect upon it and consequently change the way you act in the future. Reflection is crucial to learning from experience or from research, because it enables you to reconstruct or reorganize the experience so that you can use it (Redmond, 2006). Reflexivity derives from qualitative research methods, particularly as applied in feminist research (Finlay and Gough, 2003). It means a cyclical process, in which we study how what we observe affects our thinking and how that then affects what we do. The implication of this is that you incorporate your own and other people's reactions to an event, so that you do not take for granted your own perceptions. Reflection becomes critical when practitioners use critical social theory, which, in addition to reflexivity, does not take existing patterns of thinking and social organization for granted. This helps because it offers practitioners alternative ideas when shifting their own perceptions and those of clients and colleagues. Critical reflection has recently developed strongly in health and social care (Fook and Gardner, 2007) as both a training and a personal development device.

Through CPD, social work education continues throughout practitioners' careers, and includes programs of reading, organized personal experience, such as job swaps, shadowing a colleague with different responsibilities, short training courses, and advanced professional and academic qualifications. Advanced qualifications include advanced masters degrees and professional doctorates, which include specialized professional teaching alongside a research thesis. Social workers seeking academic roles, or wishing to undertake a substantial research project, will often complete a PhD instead of a professional doctorate.

Conclusion

Social work education is a process through which practitioners transform their personal identity by incorporating a professional identity as a social worker within it and continue to develop their identity and capacity within the profession during the whole of their career. It may be considered in three phases: prequalification training and experience, including life experience; qualifying education; and career-long CPD.

The institutional and organizational aspects of social work education brings together academic elements delivered within universities and practice elements delivered mainly in social agencies. In this way, social work education incorporates tensions between agency and university interests in controlling the curriculum and outcomes of qualifying education and CPD. The crucial issue in these tensions is the need to incorporate broader social science traditions of learning within a form of education that is also designed to train employees in the procedural and practical requirements of the role of social workers in agencies.

Social Work Ethics

Sarah Banks, Durham University, Durham, UK

Abstract

This article discusses professional ethics in social work, exploring key themes (core values, codes of ethics, ethical theories, ethical challenges, ethical decision making, and regulation of conduct) in current literature and practice. It considers whether dominant models of social work practice and ethics from the global North should be reconsidered in an international context.

Introduction

Ethics is about how human beings treat each other and the ecosystem. It covers matters of rights, responsibilities, well-being, and harm. This article explores social work ethics as a discipline-specific version of professional ethics, focusing on the conduct, character, and responsibilities of professional social workers. In the global North, 'social work ethics' is a distinct subject area in professional education and practice, marked by a growing body of specialist literature, its inclusion as a subject area in professional education, and the development of everlonger codes of ethics. While 'ethics' is less prominent in social work literature and educational curricula in the global South, interest is growing, as Anglo-American and European textbooks and models of practice are translated, adopted, and adapted worldwide.

Professional Ethics in Social Work

Professional ethics has a normative focus on how people in professional roles ought to be and behave. In early social work (casework) in late nineteenth-century Europe and North America, the focus was on the morality of service users, rather than the ethical conduct of social workers (Reamer, 2006). Concern with professional ethics grew slowly from the mid-twentieth century in the global North, as social work expanded and professionalized. The traditional model of professional ethics was premised on the idea that professionals derive considerable power from their expertise and status, and have potential to exploit, harm, or unduly influence service users. Hence, a shared set of values for social work was articulated and promoted, based on respect for the dignity of service users and their rights to make their own choices as far as possible, alongside a commitment from professionals to be trustworthy and reliable in selflessly serving fellow human beings.

The range and complexity of the subject matter of professional ethics, as reflected in professional and academic literature, has developed over time. Some themes have been remarkably consistent, although the main focus of attention may have changed. Table 1 shows key themes and a simplified interpretation of the changing content of social work ethics in the literature, which is predominantly from the global North.

Social Work Values

In discussions of social work ethics, the term 'values' is generally used to refer to ethical values – that is, particular types of beliefs about what is regarded as worthy or valuable for human welfare. For Reamer (1999: p. 3), "social work is among the most value based of all professions", grounded in "concepts such as justice and fairness" (p. 5). This relates to the purposes of social work, which in most societies include redistribution of resources and care to those in need, support for people to participate as fully as possible in society and control of people who are likely to harm themselves or others. These purposes presuppose values about human worth, people's collective responsibilities for each other, and the importance of maintaining social order. While the particular configurations of values underpinning social work and how these are expressed vary across different sources and countries, three clusters of complex values in the current social work literature can be identified (Banks, 2012a: p. 60):

1. *Respect for the dignity and worth of all human beings*: The obligation to respect each human being as an individual, treat all people as equally valuable, and respect and promote the human rights of individuals and groups to self-determination (particularly users of social worker services).
2. *Promotion of welfare or well-being*: The obligation to bring about benefits for service users and for society more generally, balancing benefits against risks of harm.
3. *Promotion of social justice*: The obligation to remove damaging inequalities between people and groups and promote the fair distribution of goods and services among people and groups.

These values may conflict, giving rise to ethical challenges for social workers. For example, respecting the rights of a 15-year-old young woman to confidentiality can conflict with the social worker's duty to promote her well-being, if her father is violent toward her. Such situations, which require sensitive decisions to be made about how to act, feature strongly in the social work ethics literature.

Codes of Ethics

Codes of ethics are key features of professions. Although what counts as a profession is contested, it is an occupation that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28030-6

Table 1 Themes in social work ethics

Themes	*Traditional focus (1960s–80s)*	*Newer focus (1990s–2010s)*
Core values – the articulation, analysis, and interpretation of the core values of the profession	Promotion of the self-determination and welfare of service users	Promotion of empowerment of service users and social justice in society
Codes of ethics – the development, analysis, and application of codified statements of principles and standards of conduct in relation to service users, employers, and society, usually incorporating or based on the core values	Short oaths based on the commitments and character of social workers	Longer documents encompassing values, principles, and standards for social work
Ethical theories – the presentation of theories of ethics derived from the literature in moral philosophy and their use to frame, explain, examine, or critique the nature of ethics in social work	Deontology (focus on duties and the nature of right action)	Utilitarianism (focus on consequences of action), virtue ethics, care ethics
Ethical challenges – the identification and discussion of common ethical difficulties faced by social workers, often framed as dilemmas and exemplified through the use of case examples from practice	Recognizing and respecting service users' rights; social workers' paternalism vs service users' autonomy	Ensuring fair distribution of resources; employer regulation vs professional autonomy
Ethical decision making – the discussion of how to make decisions in ethically challenging situations, drawing on ethical theories and codes of ethics, including the presentation and application of decision-making models or frameworks, often applied to particular cases	Professional focused, stepwise, linear models	Dialogical, circular, iterative models
Regulation of conduct – ensuring social workers conduct themselves according to the accepted values and standards of the profession	Self-regulation according to a shared vision of good social work	Development of external standards, rules, and systems of professional licensing, registration, and misconduct hearings

makes claims for status in society. Professionalizing occupations generally develop professional associations to support, guide, and protect the interests of members of the occupation and safeguard service users. Professional associations for social workers exist in the majority of countries where social work is practised, usually membership is voluntary and most have ethical codes. These are written documents covering the core purpose of the profession, its values and ethical principles, and sometimes, rules or standards of practice. Their stated aim is to guide professionals and protect service users (by laying down expectations for ethical conduct). They also serve as 'mission statements' – summarizing the essence of good social work, contributing to defining occupational boundaries, and reinforcing professional identity and status. Codes of ethics may be used in disciplinary hearings considering complaints against social workers. This is increasingly common, as regulatory bodies are established to register and regulate social work according to professional codes of ethics or practice (Banks, 2012a: pp. 107–108).

Comparison of codes of ethics for social work from professional associations in different countries shows considerable variation in length and the extent to which they include long lists of standards of practice (Banks, 2012a: pp. 112–114). However, the statements of values and ethical principles are remarkably similar. This is partly because the statement of ethical principles of the International Federation of Social Workers (IFSW) and International Association of Schools of Social Work (IASSW) (2004) is often used to develop country-level ethical codes. Furthermore, some professional associations, when newly developing their ethical codes, have drawn on codes from other countries.

Many criticisms are leveled at codes of ethics, including that their statements are too general and open to interpretation. This applies particularly to shorter codes that remain at the level of values and general principles. One response to this criticism has been to develop more specific guidance on how to act in particular situations. This can produce the opposite critique, that longer codes comprising lists of ethical standards are too prescriptive and undermine professional judgment.

Ethical Theories

In textbooks and teaching on professional ethics, an overview of theories of ethics developed by moral philosophers is common. These theories cover matters such as what counts as the good life, right and wrong conduct, and good and bad qualities of character. Many ethical theories aim to be universal (applying across all places and times) and foundational (offering a single theory that identifies what counts as 'ethical' and prescribes ethical being/action). Ethical theorists often espouse a particular theory or theoretical approach. However, in professional ethics textbooks, a range of ethical theories may be offered to provide different ways of looking at ethical problems. These may be regarded as complementary rather than mutually exclusive. The following overview of ethical theories is adapted from Banks (2012b: pp. 7–10).

Principle-Based Ethics

Until recently, modern Western literature on professional ethics focused on identifying and describing general and universal principles to guide ethical conduct. These fall into two schools of thought: deontological (duty-based) ethics, associated with the eighteenth-century German philosopher, Kant (1785/1964); and teleological (consequentialist) ethics, associated with the nineteenth-century British utilitarians, Bentham and Mill (1863/1972). Deontological or Kantian ethics is based on the ultimate principle of respect for persons as rational and self-determining beings. Any action

that fails to accord respect to each individual person (such as lying) is wrong, regardless of whether it produces good consequences. Utilitarian or consequentialist ethics, in contrast, judges the rightness and wrongness of actions according to whether they produce a greater or lesser balance of beneficial over harmful consequences for the greatest number of people. According to utilitarianism, lying might be regarded as morally right, if it resulted in a good outcome (saving life or producing a lot of happiness).

These two schools of thought are in opposition, if aiming to develop a comprehensive ethical theory based on a key foundational ethical principle. However, in everyday life, and professional practice, principles that promote respect for individual choices and rights are as important as principles that promote good outcomes for individuals and society. Statements of ethical principles and codes of ethics for social work contain both types of principle, as can be seen in the international statement of ethical principles for social work (IFSW and IASSW, 2004). Arguably, some of the more challenging ethical dilemmas in social work lie in deciding when to compromise respect for an individual's right to freedom of choice and action to promote what is considered their greater good or the greater good of others or society in general.

According to principle-based approaches, ethical decision making is a rational process that involves applying general principles to particular cases. Decision makers should treat all similar cases in a like manner, as impartially and objectively as possible.

Character- and Relationship-Based Approaches to Ethics

There are alternative theoretical approaches to ethics that start with particular people and situations. Virtue ethics, for example, focuses on the qualities of character of the moral agent, and asks not "what should I do?" but "what kind of person should I be?" and "what would a good person do in this situation?" (Banks and Gallagher, 2009; Hursthouse, 1999; Swanton, 2003). A focus on the development of good qualities of character can be found in many ancient Eastern religious teachings, including the works of Confucius and Mencius, and Buddhist texts. According to Gyekye (2010), character also forms the basis of African ethics. In Western philosophy, virtue ethics is associated with the ancient Greek philosopher, Aristotle (350 BCE/1954), and later developments by Christian religious philosophers, Aquinas and Augustine. After declining in popularity, virtue ethics has recently undergone a revival in Western ethics, to complement or replace more abstract, principle-based approaches to ethics.

Other situated approaches to ethics include the ethics of care (Tronto, 1993; Held, 2006), which focuses on relationships between people and particular responsibilities inherent in special relationships (like mother and child); and the ethics of proximity, based on responsibilities experienced in face-to-face encounters between one person and another (Vetlesen, 1997; Levinas, 1989). The emphasis on relationships and responsibilities brings these approaches much closer to ways of thinking prevalent in the global South, where individuals are defined in relationship with others. Here, much less emphasis is placed on the individual or relationships between individuals per se, but rather the focus is on the community (communitarian ethics), seeking solidarity, harmony, and common good.

Narrative and Case-Based Ethics

Approaches to ethics that give primacy to character, relationships, and communities often use stories as a methodology. According to Nelson (1997), these stories: heighten moral perception and sensitivity; promote moral education; provide ethical justification; define one's moral identity; and make ethical evaluations through comparing stories. The term 'narrative ethics' refers to a cluster of methodologies that use stories, rather than a theoretical approach to ethics.

'Casuistry' or case-based ethical reasoning (Jonsen and Toulmin, 1988), sometimes grouped under the heading of 'narrative ethics,' is also a distinctive approach in its own right (a revival of a medieval Christian practice of providing moral guidance in particular situations). Rather than starting with ethical theory, casuistry begins with particular cases, taking into account the specific circumstances of each case in deciding what an ethically correct response might be. It works by taking a paradigm case, which is relatively straightforward and about which most people would agree in their ethical evaluations, and then compares the case at hand with the paradigm case to determine differences and similarities. This is analogous to the approach taken in legal reasoning, and requires skills in determining the morally relevant features of cases and creating taxonomies of types of cases and issues. Casuistry is not a normative theory (prescribing what is good or bad), but more like a method for making ethical assessments and decisions. In case-based ethics, 'moral reasoning' plays a crucial role. 'Reasoning' in this sense includes the use of moral intuition and practical wisdom and is not the same as rationality based on abstract principles.

If seeking an internationally relevant approach to social work ethics, this approach to ethical evaluation is helpful in that it starts with the case and advocates pursuing a detailed and careful analysis (Banks, 2012b). Sometimes people who espouse very different ethical and religious values may agree about what should be done in a particular case, by focusing on its details. Their differences emerge when they justify their ethical evaluations with reference to different values or theories.

Ethical Challenges

Social workers often play a role within welfare systems designed to care for, control, educate, or empower people. This inevitably leads to contradictory imperatives and ethical challenges (Dominelli, 2004, 2010). The key values and principles identified earlier may conflict and social workers have to make difficult choices regarding how to act and what roles to play. The literature frequently refers to ethical dilemmas and problems – difficult choices with no easy solution, where the rights, needs, and interests of different parties conflict. Yet it is also important to see social work as an occupation that has ethical issues embedded within everyday practice (not just when difficult choices have to be made). In considering the form of ethical challenges, a distinction can

be made among ethical issues, problems, and dilemmas (adapted from Banks, 2012a: p. 20):

- *Ethical issues* – pervade social work (including what appear to be 'legal' or 'technical' matters) in that practice frequently takes place in the context of state systems of welfare premised on principles of social justice and public good and social workers have professional power in the relationship with service users. For example, deciding whether to recommend home care services for a person with a disability in a straightforward case may not involve a social worker in agonizing over an ethical dilemma, but it is not devoid of ethical content (the service is premised on principles of care and distributive justice).
- *Ethical problems* – arise when a social worker sees a situation as involving a difficult ethical decision, but is clear about the right course of action. For example, the worker may decide to reject the application of a very needy person for home care services because this person does not fit the criteria.
- *Ethical dilemmas* – occur when a social worker sees himself or herself as facing a choice between two equally unwelcome alternatives, which may involve a conflict of ethical values, and it is not clear which choice will be the right one. For example, should the practitioner bend the rules for allocating home care services to help a very needy person, or follow the criteria and refuse the application? The worker is faced with a conflict between the interests of this individual and the public interest in having rules and criteria that apply to everyone.

Ethical Decision Making

Textbooks on social work ethics often include significant sections on deciding how to act in difficult situations (e.g., Bowles et al., 2006; Dolgoff et el., 2012; Reamer, 2006). The social worker is presented as an active moral agent, guided by ethical principles and making a critical interpretation of relevant ethical codes. The focus is on professionals and their internal reasoning processes, or on the reasoning processes of members of a professional team. Ethical difficulties are frequently framed as 'ethical dilemmas' and presented as cases, with readers invited to consider what decision they would make in such a situation, as the following short invented case illustrates:

Case 1: Deciding whether to accept a donation

The staff team running a domestic violence shelter has to decide whether to accept or refuse urgently needed funding from a private company. Accepting the money would contribute immediately to promoting and supporting the shelter's work on women's safety and welfare in a very violent neighborhood. Arguments for refusal include the fact that the company runs lap-dancing clubs (erotic dancing) and may gain credibility from being associated with the shelter. These links may undermine the shelter's values and integrity in the longer term.

To help students analyze cases and develop skills in ethical decision making, it is common to offer models, often leading the reader through a series of questions. There are numerous examples, ranging from those comprising a linear, stepwise process to more holistic, circular models (for a useful review, see McAuliffe and Chenoweth, 2007).

One commonly quoted linear approach is the five-step ETHIC model proposed by Congress (1999):

1. Examine personal, cultural, societal, client, agency, and professional values;
2. Think about the various UN declarations on rights and related covenants, codes of ethics, laws and agency regulations;
3. Hypothesize different courses of action based on varied decisions;
4. Identify who is most vulnerable, who will be harmed or helped; and
5. Consult with supervisors and colleagues.

These steps can encourage analysis of the issues at stake, although their simple structure masks the complexity of the range of different perspectives and factors, including emotional dimensions, and how to negotiate between them. It also does not take account of the importance of an iterative cycle of reflection and learning.

To counteract such limitations, McAuliffe and Chenoweth (2007) propose an 'inclusive' circular model, taking account of core social work values, based on four interlinked 'platforms' for good decision making (accountability, consultation, cultural sensitivity, and critical reflection), which includes the following steps:

- defining the ethical dilemma;
- mapping legitimacy (who has a legitimate stake in the decision-making process);
- gathering information;
- assessing alternative approaches and actions; and
- critical analysis and evaluation.

Decision-making models encourage systematic, comprehensive, and analytical thinking about the range of factors to be considered in making difficult ethical decisions and can be helpful in teaching and learning about ethical reasoning. However, in everyday practice, the many moment-to-moment small 'decisions' that are made about how to proceed may be quite intuitive and hardly recognized as decisions unless social workers are asked to justify or explain afterwards what they did and why. Hence, the focus of textbooks and teaching in professional ethics needs to extend beyond dilemmas and decision making.

Regulation of Conduct

The traditional emphasis in professional ethics on ethical decision making assumes that social workers are active moral agents engaged in making considered decisions based not only on regulations, laws, and codes, but also on their appraisal of the relevant professional values at stake and evaluations of people's rights, needs, and interests. In a climate of new managerialism and economic austerity, social workers are required to be more accountable for their actions and demonstrate effectiveness and

value for money, as well as ethical conduct. In many countries, especially in the global North, tighter regulations have been introduced to ensure efficiency and ethical conduct (Banks, 2011; Harris, 2003). In several countries, statutory regulatory bodies have been established for social work, the functions of which include maintaining a register of qualified professionals – with the power to remove people from the register if incompetence or unethical behavior is proven (Orme and Rennie, 2006). Regulatory bodies may protect the title, 'social worker' (only those registered can practise as social workers) and play a major role in licensing social workers and disciplining them on grounds of professional misconduct.

There is a slow trend toward statutory regulation of social work as an occupation with a protected title. Many in the profession welcome regulation as a contribution toward gaining occupational recognition and status. Others are skeptical of the benefits, recognizing that these carry the price of increasing state control and prescribing the conduct of individual social workers. The autonomy of the profession, and of professional associations, is reduced in the interests of maintaining and developing the credibility of the profession and standardizing practice. 'Ethics' comes to be associated with following predetermined rules or standards, rather than considered decision making and reflection (Banks, 2004, 2013a).

From Professional Ethics to Ethics in Professional Life

This article has focused largely on normative professional ethics – how social workers should be and act in work contexts. It is impossible to separate theoretical and practical prescriptions of what practitioners ought to do from accounts of what social workers actually do and say. While textbooks focus on normative professional ethics, there is an increasing research interest in 'empirical ethics' – studies of what people do and say in practice in relation to matters of rights, responsibilities, harms, and benefits. This may take the form of surveys to find out what people think about certain types of behavior (e.g., whether it is right to lend money to service users) and reports of actions they have taken (e.g., whether they have ever lent money to service users) or qualitative research studies involving interviews and/or observations relating to everyday practice. In ethnographic research, the ethical dimensions of social work are embedded in everyday practice and have to be identified and 'extracted' by research participants and/or researchers. This can lead to a different conception of ethics than found in normative textbook ethics, encouraging a view of ethics as involving emotion *and* rationality (e.g., empathy, fear, anger). It also encourages a view of ethics as embodied (a physical side to ethical being and acting); embedded (ethical norms are deeply contextualized in communities, organizations, and wider cultures and responsibilities relating to particular relationships); and evolving (created through dialog and relationships with others).

Approaching ethics as a situated practice resonates with theoretical approaches that focus on character, care, communities, and narratives, and is encapsulated in Margaret Urban Walker's (2007) 'expressive-collaborative' model of ethics. On this view, ethics is "a socially embodied medium of understanding and adjustment in which people account to each other for the identities, relationships, and values that define their responsibilities" (Walker, 2007: pp. 67–68). According to Walker, ethical life is a continuing negotiation among people. This contrasts with the dominant type of ethical theory, which presents a 'theoretical-juridical' model of ethics as a codifiable set of moral formulae to be applied by any agent in making a specific, justified action-guiding judgment (Walker, 2007: pp. 58–59). In the context of social work ethics, this implies a broadening of traditional normative professional ethics (focusing on abstract ethical principles, ethical dilemmas, ethical decision making, and, increasingly, ethical regulation) to what I have called elsewhere 'ethics in professional life' – seeing professional life as an ethical practice and ethical issues as embedded and embodied in everyday being and doing (Banks, 2010).

The Dangers of Imperialism in Ethics

In many countries in the Southern world, the 'expressive-collaborative' approach to ethics makes more sense than the 'theoretical-juridical' approach. The identification and abstraction of a dimension of practice that can be labeled 'ethical' may be quite challenging in some cultural contexts, especially if there is no specific word easily translatable as 'ethics' (as seems the case in many African languages). The growth of the 'ethics industry' in the North, including the production of textbooks, international codes of ethics, and specialized teaching modules, may entail exporting decontextualized models of ethics and sets of principles and rules that do not necessarily fit comfortably everywhere (Hugman, 2008; Ife, 2008). While the formulation of international principles that promotes respect for human dignity, human rights, and social justice is important and welcomed by social work practitioners in many countries, the theoretical-juridical model is just one approach to ethics. This presents a challenge, as it requires academics and practitioners to be alert to imperialism in ethics (transferring Northern values and approaches to the Southern world), while avoiding ethical and cultural relativism (uncritically accepting practices based on local norms). This challenge is exemplified in case 2 (summarized from Banks and Nøhr, 2012: pp. 91–94).

Case 2: A Dutch student in Vietnam

A Dutch social work student was undertaking fieldwork practice in a rehabilitation hospital in Vietnam. She accompanied two physiotherapists on a home visit to an 8-year-old boy, Trung, who had Duchenne Muscular Dystrophy (DMD, a severe form of muscular dystrophy characterised by rapid muscle degeneration). Trung was in a wheelchair, writing on a small table attached to the chair. His mother proudly talked about the school prize he had won for his handwriting and Trung talked about his favorite activities. His mother asked when there would be an improvement in Trung's physical condition. One of the physiotherapists said he did not know, and that Trung should keep doing his exercises.

On returning to the hospital the student asked the staff if any improvement was possible with DMD. They replied 'no'. There was a possibility that Trung did not have a long life ahead. However, it

was better that Trung and his parents did not know this, otherwise they would feel sad.

The student entered into a discussion, explaining that this was contrary to her social work ethics and that in the Netherlands professionals try to be open and honest about a patient's medical situation. By not telling the family the truth, the family did not have the chance to overcome the pain that comes with the prognosis. She recognised that this approach was culturally linked, but wondered if it was based on lack of knowledge, including not knowing how to deliver bad news. The physiotherapists were interested in the Dutch way of handling such situations, just as the student was interested in the physiotherapists' explanation that in Vietnam discussing a terminal illness with patients and families causes unnecessary misery.

For the Dutch student and Vietnamese physiotherapists (and all health and social care professionals) 'ethics' is an ongoing project. Referring to European ethical codes and textbooks may offer conceptual frameworks and point to issues to consider. However, these frameworks must be critically interpreted and located in the political and cultural context of specific countries and in relation to the aims, purposes, and ways of working of the relevant agencies. Being ethical in this case is not just about making decisions according to principles or following rules, but requires practitioners to engage in ongoing dialogs with themselves, their colleagues, and broader society – an 'expressive-collaborative' practice.

Concluding Comments

Social work ethics is about challenges and contradictions in everyday practice. There are no easy formulae for tackling challenges or resolving contradictions, although ethical codes and decision-making models may provide some guidance. Acting ethically and being ethical is an ongoing project that entails a process of critical reflexivity (being aware of the social and political contexts in which one is working and recognizing one's own position, role, and power). This can be described as 'ethics work' (Banks, 2013a). It involves emotions as well as reason; the development of qualities of character as well as decision-making skills; and an ability to live with and negotiate the inevitable ethical tensions in the work. Given social workers' roles at the interface of state welfare and social control, it requires moral courage for social workers to speak out against injustices and to resist becoming highly regulated administrators of evertighter welfare budgets. Social work is also inherently political (Banks, 2013b; Dominelli, 2010; Ferguson, 2008). The political dimensions of social work are inseparable from the ethical. This entails a collective commitment to working for human rights and social justice, and a conceptualization of social work as not only a socially useful and value-based profession, but also a worldwide social movement concerned to advocate alongside and for service users, and those who need services but are excluded.

Social Work in China

Abstract

Social work, first introduced to China in the 1920s, was eliminated as an academic discipline and profession in the early 1950s, and restored in the late 1980s to respond to a growing demand for social workers to resolve escalating social problems triggered by the open-door economic policy. In 2006, the Chinese government announced the formation of strong social work teams to develop a harmonious society, an initiative reinforced by national policies and plans supporting the profession's development countrywide. The authors highlight the evolution of social work post-1920: the background and events surrounding its reemergence; challenges; opportunities; and prospects for future development.

Introduction

Social work was first introduced in China in the 1920s, but was eliminated both as a university discipline and as a profession in the early 1950s. After a lapse of over 30 years, social work was restored to the university curriculum in 1987 because of the growing need for social work professionals to help in resolving escalating social problems triggered by the introduction of the open-door economic policy in 1979. At the same time, social work services were gradually reintroduced by the Ministry of Civil Affairs and other related government departments and NGOs. In 2006, it was announced during the Sixteenth Congress of the Chinese Communist Party that China needed to develop a strong team of social workers to serve the escalating social needs of the country. Subsequent to the announcement, social work as a profession has undergone phenomenal growth in China. The strategic plan jointly issued by 19 National Ministries and Committees of China, 'The Medium and Long Term Social Work Professional Talent Development Plan (2011–20),' has further reinforced this trend and consolidated the development of social work as a profession in China.

Stages of Development of Social Work

The Emergence of Social Work in the 1920s

In China, social work as philanthropy dated back to very early times. It included all kinds of social relief and social services provided by governments as well as private and religious organizations and had a strong flavor of paternalism. The beginning of professional social work could be linked to the introduction of the Young Men's Christian Association (YMCA) in the 1880s, when the first YMCA officers organized comprehensive religious activities and social services for young people in the cities of Tientsin and Beijing with the aim to alleviate social problems and promote social reform (Jun, 1996; Pang, 2010). In 1922, Yenching University (Peking University) established its Department of Sociology, and in 1925 it was renamed the Department of Sociology and Social Service, thus marking the official introduction of social work as a discipline to the university curriculum in China. Social work–related subjects such as casework, group work, social administration, social welfare, and mental health social work were taught in the university curriculum (Pang, 2010). Besides teaching social work subjects in the classroom, Yenching University established the Ch'ing Ho Fieldwork Base and provided a valuable arena for teachers and students to apply their knowledge and skills in social work practice (Xia and Guo, 2002). Many other social work education programs and social work subjects were subsequently introduced to other leading universities, including Fudan University, Furen University, Jinling University, Lingnan University, and Hu Jiang University. Graduates of these programs served in social services organizations such as the YMCA, YWCA, hospitals, schools for blind people and deaf people, mental health institutions, prisons, orphanages, relief organizations, and rural community service agencies (Pang, 2010).

Abolition of Social Work in the 1950s

Shortly after the establishment of the People's Republic of China (PRC) in 1949, China adopted the Soviet model of socialism and created a centralized planned economy with a view to eliminate class oppression, inequality, and social injustices in society. During the period of planned economy, social work as a profession was totally eliminated from the government establishment and the practical field of social welfare services. All social work programs were removed from universities during the 'restructuring of institutions of higher learning' in 1952 because it was claimed that social problems would no longer exist in a Socialist society and therefore there was no need for the continuation of social work education in the country (Lei and Shui, 1991).

In this stage of development, the government was the sole provider of social welfare services and social service functions were redistributed among the Ministries of Civil Affairs, Labor, and Health, as well as among state-sponsored national organizations such as the National Women's League, the National Labor Union, and the Communist Youth Corp (Wang, 1995). The Socialist 'from cradle to grave' welfare package provided the employees of state-owned enterprises with a wide range of social protection, including pensions, health care, housing, education, and other essential social services. Residual services

for vulnerable groups including elders, orphans, the handicapped, and mentally ill persons who did not have families or work units, were taken care of by the Ministry of Civil Affairs. During this period, the previously vibrant social work community virtually vanished from the scene and social workers trained in the earlier stage were dispersed to numerous work units, some related to social services and some with no direct relevance to social work (Yuen-Tsang and Wang, 2008).

Reemergence of Social Work in the Late 1980s

The introduction of China's 'open door' economic reform in 1978 by reformists within the Communist Party of China led by Deng Xiaoping steered China away from a welfare state model toward the neo-liberal welfare model, based mainly on economic efficiency and aimed at providing only basic welfare benefits to maintain social stability. It was anticipated that there would be a significant reemergence of social inequality and class divisions (Leung and Nann, 1995; Preston and Haacke, 2003). In view of the escalation of social problems, some leading academic and political leaders who were previously trained in social work and applied sociology such as Lei Jieqiong and Fei Xiaotong (Lei and Shui, 1991) fervently advocated the reintroduction of social work as a discipline into the university curriculum. In 1987, the Ministry of Civil Affairs, together with the State Education Committee discussed the restoration of social work education in China and eventually reached a joint decision that the Ministry of Civil Affairs was to invest 1 million RMB (renminbi) in the Department of Sociology of Peking University, so that Peking University could take the lead in reinstating social work education in China.

In the summer of 1988, the Asia Pacific Association of Social Work Education (APASWE) and Peking University co-organized a Seminar of the Asian-Pacific Region Social Work Education in Beijing which was attended by over 160 delegates from the region of whom over 100 were Chinese educators and officials interested in reintroducing social work education in China (Xia and Guo, 2002; Xiong and Wang, 2007). Following the admission of the first batch of social work degree and MPhil students to Peking University in 1989, many other universities and colleges such as Jilin University, Xiamen University, the China Civil Affairs Cadre College, the China College of Youth Politics, China Women's College, Yunnan University, Nankai University, and East China University of Science and Technology also started their social work programs in the early 1990s. The China Association of Social Work Education (CASWE) was formed in 1994 to strengthen the network among schools of social work in China and foster the advancement of social work education in China. During this period, social work schools in Hong Kong and Taiwan played a pivotal role in supporting the development of social work education in China through the provision of books and teaching materials, short-term 'training of trainers,' programmes, attachment opportunities, MPhil, and PhD scholarships, and the organization of regular seminars and conferences for exchange purposes (Yuen-Tsang, 1996).

The period also witnessed the reemergence of social work services in China. The gradual demise of the work units (*danweis*) together with the comprehensive welfare system during the reform era had called for the development of community support services for those without welfare coverage. The Ministry of Civil Affairs pioneered many community-based social services, such as meals-on-wheels, home-help services, daycare centers for elderly people; and developed long-term collaborative relationships with social service agencies in Hong Kong to enhance the quality of its services. In 1991, the Ministry of Civil Affairs established the China Association of Social Workers (CASW) with the purpose of fostering the professional development of social work in China, and in 1992, the CASW became an institutional member of the International Federation of Social Workers (IFSW) with the purpose of promoting connections with the international social work community (Wang, 2012).

Rapid Expansion and Professionalization of Social Work Since 1999

The development of social work since 1999 was phenomenal and was commonly regarded by social workers as the 'Spring of Social Work' in China. In 2003, Hu Jintao and Wen Jiabao took over as the fourth generation leadership of China as President and Premier, respectively, and shifted China's ruling ideology from one that only focused on economic growth to one that emphasized overall societal development. When they took office, they inherited a China wrought with internal social, political, and environmental challenges. One of the biggest problems was the increasing wealth disparity between poor and rich people in China, for which discontent and anger mounted to a degree that seriously challenged the leadership of the Chinese Communist Party (CCP). In response, the CCP proposed the 'Scientific Development Perspective' as the fundamental guiding principle in economic and social development. This emphasized a synergetic relationship between economic growth and social development; between urban and rural development; and between economic development and environmental protection (Wang, 2012; Yuen-Tsang and Wang, 2008). Consequently, the government developed a series of social policies to alleviate urban and rural poverty and provide basic social, economic, and medical protection for the masses. The abundance of social policy initiatives introduced was unprecedented and this period was regarded by some scholars as 'The Age of Social Policy' (Wang, 2004). In 2006, Hu released the document on 'The Decision Concerning Several Major Problems in Building a Socialist Harmonious Society' during the Sixteenth Central Committee of the CCP, spelling out the need for establishing 'a grand team of professional social workers to help in building a harmonious society,' and proposed the fundamental regulations of training, evaluating, recruiting, and stimulating professional social workers. This policy marked a new chapter in the development of social work in China and spearheaded the professionalization process for social work in China.

The higher education reform in 1999 accelerated the drastic expansion of social work education programs. While there were only four universities offering social work programs in 1988 and 24 in 1999, the number rose to 36 in 2001 and soared to 186 in 2006 and 262 in 2012, graduating over 10 000 students per year (China Association of Social Work Education, 2012). But the shortage of social work educators who had undergone

professional social work education was an issue of grave concern. In 2000, in response to the urgent need to develop a critical mass of social work educators who could effectively assume leadership roles in spearheading the future development of social work education in China, the Hong Kong Polytechnic University and Peking University developed the first Master of Social Work (MSW) Program in 2000 (Xiong and Wang, 2007). Between 2000 and 2012, the Programme nurtured over 200 graduates who undertook key leadership positions in higher education and social welfare organizations, and played influential roles in advancing social work education as well as social work development in China. In 2009, the Ministry of Education announced the launch of China's own MSW Programs and 33 renowned universities from different parts of China were granted permission to offer Masters programs. By 2012, a total of 61 universities were given approval by the Ministry of Education of China to offer MSW programs (Liu, 2012).

The development of professional social services during the period was also extremely rapid. In 1997, the Pudong district of Shanghai had taken the lead to launch pilot social work practice sites and established NGOs to provide professional social work services including school social work, youth outreach service, mental health service, and services for street children (Wang, 2012). Subsequently, many major cities such as Shanghai, Beijing, Tianjin, Wuhan, Changsha, and Guangzhou piloted various social service models and developed demonstration projects. The experience of these pilot projects were shared among members of the social work community through national seminars and publications, and had significant impact on the professionalization of social work in China (Wang, 2012).

In terms of policy support, the Chinese government was extremely progressive. In 2006, the Ministry of Civil Affairs and the Ministry of Personnel of China and other ministries jointly issued the 'Provisional Regulations on the Assessment of the Vocational Standards of Social Workers' and 'Measures for the Implementation of the Examination Regarding Professional Qualifications of Social Workers' with a view to establishing at the national level, a system for the assessment of the professional standards of social workers. These two documents signified that social work would be recognized as a profession in the Chinese mainland and that measures would be taken to develop a nationally recognized career ladder for social workers with clearly stipulated vocational levels and expectations (China Association of Social Work, 2009). In 2009, the Ministry of Civil Affairs announced the document 'Concerning Continuing Education Arrangements for Social Workers,' providing guidance and monitoring mechanisms for continuing education for social workers and stipulating that all those with Assistant Social Worker and Social Worker professional qualifications had to obtain at least 72 and 90 h (respectively) of continuing professional education during the three-year registration period. In 2009, the Ministry of Civil Affairs issued the document, 'Announcement Concerning the Fostering of the Development of Nongovernmental Social Work Organizations' which introduced measures to enhance the management, supervision, and systematic development of social NGOs in China. In 2012, the Ministry of Civil Affairs and the Ministry of Finance of China jointly issued a policy paper on the purchase of social work services, providing guidelines and measures for the use of public funding to purchase social services provided by NGOs to serve the needy and vulnerable sections of the population.

The most significant policy paper which is regarded as the watershed in the professionalization of social work in China is the '2011–20 Medium Long-term Strategic Plan on the Development of Social Work Professional Manpower Team' issued in 2012 by 19 Ministries and Committees in China. The policy paper confirmed the urgent need to develop professional labor power to support the development of a harmonious society in China and stipulated a target to train 500 000 social workers by 2015, and 1 450 000 social workers by 2020. The policy paper outlined the systematic strategies to be adopted by the government to train different levels of professional social work personnel and the measures to be taken to support, train, monitor, and evaluate the quality of social work manpower nurtured through this process. The policy paper was received with great excitement and joy by the social work community in China and it is expected that the social work profession will be greatly strengthened through the process and will be able to make significant impact on social betterment in China.

Salient Features of the Development of Social Work

Strong Leadership Role of the Government

The Chinese government has played a pivotal role in supporting the development of social work in the country. Despite the phenomenal economic achievements brought about by the introduction of market economy, social problems and social conflicts have accelerated. At the turn of the century, critical social issues including the widening gap between rich and poor people, disparity between urban and rural areas, corruption, environmental contamination, and ethnic conflicts had reached alarming levels. President Hu Jintao's 2004 announcement to adopt the 'harmonious society' as the guiding principle to develop the country, and the subsequent pronouncement in 2006 of the national policy to develop 'a grand team of professional social workers to help build a harmonious society' reflected the Chinese government's determination to address escalating social problems through different types of social work interventions (Liu, 2012; Xiao, 2009). Measures introduced by the government to enhance social work development include developing social work positions in different levels of government; supporting the establishment of NGOs; supporting the development of social work education programs at the post-secondary, degree, and MSW levels; and developing pilot projects on services for different target populations (Liu, 2012). The government sees its role as the main provider of social welfare resources with the aim of serving its people and gaining legitimacy for social governance. As such, it has been predicted that the Chinese government will remain the preeminent agent in setting social policies and designing and providing social services; and will also be the major employer of practitioners performing social work and social service functions in China (Tsang et al., 2008; Wang, 2004).

Social Work Education as a Catalyst for Social Change and Development

The active involvement of social work educators and the CASWE had been pivotal to the professionalization process of social work in China (Wang, 2012; Yuen-Tsang and Wang, 2008; Shi, 2012). Since the 1990s, key actors in CASWE have been extremely proactive in seizing all opportunities to promote social work and influencing government policies to recognize social work as a profession in China. The CASWE formed both regional and national networks among social work educators to facilitate communication; conducted training workshops to enhance professional competence among educators; developed practicum sites to provide quality fieldwork placements for students; arranged overseas exchange programs for educators and students; published social work textbooks to encourage the development of indigenous teaching materials; organized national and international conferences to encourage sharing and collaboration; conducted reviews on social work programs to assure quality; and provided consultation to the government on policies relating to social work and social work education. Moreover, in almost all the national task forces and commissions relating to social work and social work education, the government involved social work educators as consultants and experts and took their recommendations seriously in their deliberations. The role of social work educators in China as the catalyst steering the direction of the development of social work in China is evident.

Active Agency of the Social Work Community in Coconstructing the Social Work Profession

The strong partnership relationship among members of the social work community, including educators, government officials, nongovernmental organization leaders, and front-line practitioners, has also played a significant role in facilitating the development and coconstruction of a social work profession appropriate to the Chinese context. Key stakeholders of the social work community had interacted in a dynamic manner to promote and coconstruct the social work profession (Wang, 2012). They were close allies in promoting social work in the country and leverageding each other to develop policies and practices appropriate to the Chinese context. While the social work educators took active steps to generate social work practice theories and models through action research and pilot projects and influence policy formulation through consultation processes, many initiatives spearheaded by local governments and NGOs also contributed to the development of demonstration projects that impacted national service development. The active agency of the entire social work community in China throughout the past two decades has been instrumental in facilitating the professionalization process and the coconstruction of a social work profession appropriate to the sociocultural context of contemporary China (Yuen-Tsang and Wang, 2008).

Emphasis on the Indigenization of Social Work in the Chinese Context

During the early 1990s when social work was reintroduced in China, there was strong temptation for Chinese social work educators and social workers to borrow social work curricula and practice models without any change, from foreign countries. Some social work educators zealously advocated the adoption of a national social work curriculum to be modeled after the standard curriculum already developed in countries such as the United States and the United Kingdom. The tension and debates on whether to follow global trends and standards or develop indigenous theories and practice appropriate to the local context had been active in the profession since its reintroduction in China. While some believed that social work should follow international standards and could borrow directly from overseas models, those who advocated the use of the indigenous approach were convinced of the need to identify knowledge as understood and experienced by people within its own culture and felt that steps had to be taken to understand psychological and social phenomena as they existed within their cultural contexts (Bond and Hwang, 1986; Ge, 2004; Kim and Berry, 1993; Yang, 1999). Most leaders of the Chinese social work community appeared to have subscribed to the view that international experience should be integrated within the practical reality of China and that serious efforts should be made to indigenize social work practice in China's contemporary sociocultural context (Tsang and Yan, 2001; Wang, 1988). This discourse strongly influenced the subsequent development of social work in China and many experiments, such as the 'Shanghai model' and 'Shenzhen model,' were launched with the aim of discovering social work practice models appropriate to the cultural context of contemporary China.

Opportunities and Challenges Confronting the Future Development of Social Work

The development of social work in China seems to be extremely promising in view of the significant role that the profession is expected to play in national development. However, there are many critical issues confronting the profession which must be seriously tackled before the profession can achieve its expected goals and bring about the anticipated impact.

Regional Disparities in Social Work Development

The regional disparity between different regions in China is extremely wide. While the economic advancement in the coastal regions has been phenomenal since the introduction of the open-door economic policy, economic development in many parts of the Middle and Western regions of China remains seriously inadequate. These regional disparities have given rise to imbalanced development not only in the economic sphere but also in social development and welfare provisions (Shi, 2012). The widening gap between the income and living standards of urban and rural populations has been further aggravated by globalization processes (Zheng, 2010). The marginalized living experience of migrant workers in urban areas as a result of their lack of the official *hukou* (household registration) status in the cities and their consequent ineligibility to access government welfare and education provisions (Cheng and Selden, 1994; Fan, 2008; Wong et al., 2007) had

given rise to growing resentment and resistance among migrant workers (Chan and Pun, 2009; Pun et al., 2009; Pun and Lu, 2010). The magnitude of problems confronting local populations in the poorer regions has given rise to conflicts and discontent and may become sources of civil unrest. As such, the government is seriously contemplating the development of measures to redress such issues and ensure social harmony. The provision of welfare benefits and social work services is one of the viable options. But the relative lack of resources in these regions and the shortage of professional social work personnel have made it extremely difficult to develop the needed social work services in these localities. It is, therefore, a matter of urgency to develop a system of social work education and social services which is appropriate for the poorer regions of China to redress regional imbalances and provide needed assistance to help them alleviate poverty, address social problems, build local capacity, and enhance social harmony.

Tension between Meeting Needs of the Masses and the Demand for Professionalization

Another critical issue is the tension between the quantity and quality of social work education programs and social work services to be provided. Given the huge population of China and the complexity of its social problems, it is extremely difficult to provide adequate social work services for the majority of the population. The recently announced policy of the Chinese government on the '2011–20 Medium Long-term Strategic Plan on the Development of Social Work Professional Manpower Team' with the ambitious goal of training 500 000 professional social workers by 2015, and 1 450 000 social workers by 2020 is an indication of the urgent need for professional social workers to provide social services for the population. But given the lack of adequate qualified social work educators to provide training for the social work trainees; the lack of a system of well-established social services units and organizations to provide quality practicum sites; and the lack of a vibrant social work professional culture in China, it is doubtful whether the desired target could be reached in an effective manner. The need to satisfy the basic social service needs of the country within a short period of time will create tensions between quantity and quality and will require compromises.

Tension between Westernization and Indigenization

The constant tension between the tendency to borrow directly from the West and need to search for local practice models which are culturally appropriate has been a regular feature of the Chinese social work community since the early years of the profession's reintroduction in China. The tension seems to have resurfaced in recent years because of the sudden growth of social work education programs and social services in China following the government announcement of policies to professionalize social work. The high percentage of teachers of the newly approved MSW programs who have not gone through professional social work education themselves and their relative lack of direct supervised practice experience may negatively affect their ability to integrate theory with practice and to teach social work in a culturally sensitive manner.

Similar tensions are surfacing in the direct practice arena because of the sudden upsurge of government supported NGOs in China. As a response to the government's newly introduced 'purchased service policy,' many NGOs have been established during the past few years to provide services for needy service users. While the service workers of most of these newly developed NGOs are highly motivated, many of them have received little professional training and their organizations do not have well-established management structures and professional support services. As a result, the tendency to borrow directly from existing practice models developed in the West has become common practice. Being acutely aware of the problem, the government has been encouraging university social work departments to form their own NGOs or to actively engage with NGOs in order to provide placements for their students and at the same time provide services for specific target groups. This approach will hopefully encourage social work educators to engage in direct practice together with their students, and will help in generating local social work practice theories through the process.

Lack of a Strong Knowledge Base to Support the Rapid Development of Social Work

The reintroduction of social work to China only took place in the late 1980s and the profession was not given much recognition and support until very recently. During the past two decades, the social work academic community was very weak in terms of size, status, and social recognition as compared to other academic disciplines in the academy and social work was perceived as an applied discipline which did not require the support of rigorous research activities. Consequently, the resources devoted to supporting the development of social work were extremely limited and social work educators had encountered great difficulties in securing financial, personnel, and other resources to support their academic and scholarly activities. The relative lack of a strong knowledge base to support the rapid development of the profession negatively affected the quality of services to be provided and thus the inability of planned services to achieve intended objectives. Serious and systematic efforts are therefore urgently required to enable social work educators and practitioners to generate social work theories and practice models which are firmly grounded in solid practice research, with a view to providing strong theoretical support to guide the future development of professional social work practice in China.

Conclusion

The development of social work in China has gone through dramatic changes since its introduction in the early 1920s. Members of the social work community have been active agents in facilitating positive social change and development in society and have made significant impact on social work education, practice, and policy advocacy during different historical periods. They have not only responded to issues emerging in their particular historical and social contexts, but also contributed significantly to the professionalization of social work in the country through practice innovation, theory

building, and policy advocacy. Even though the social work profession in China is still in an early stage of development and there are numerous issues and challenges waiting to be addressed, it seems that the social work community is ready to take up the challenge with vision, determination, and high motivation. It is expected that the development of social work in China will be extremely promising not only in terms of quantity and scope, but also in terms of quality and social impact. Moreover, it is envisaged that social work development in China will not only contribute to social betterment within its own country, but may also have significant impact on and contribution to the development of social work worldwide.

Social Work in Eastern Europe

Darja Zaviršek, University of Ljubljana, Ljubljana, Slovenia

Abstract

Historical, economic, and social differences as well as common experiences of state socialism in Eastern Europe made social work a profession with many commonalities and differences across the region. With some exceptions, university-based social work education began after 1991. Modern social policies and social work practices have developed during the time of transition from communism to a free market, which produced economic hardship, ethnic wars, racism against ethnic minorities silenced under communism reemerging, increased social inequalities, large-scale migration, and a new understanding of individual needs and people's everyday desires, all reflected in social work practice.

Introduction

Eastern Europe politically and socially is part of Europe (although not always the case geographically) and encompassed countries embedded in state socialism as the dominant political system for approximately 50 years. These include former Soviet Union republics – Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Moldova, Russian Federation, Tajikistan, Turkmenistan, Ukraine, Uzbekistan, Albania, Bosnia and Herzegovina, Kosovo, Macedonia, Montenegro, Serbia, and countries that have become part of the European Union in 2004 (Czech Republic, Hungary, Poland, Slovenia, and Slovakia, including the three Baltic countries already mentioned), in 2007 (Bulgaria, Romania), and in 2013 (Croatia).

Their communist past has been an important marker that influences today's social work education, social welfare institutions, and social work knowledge and practice, but it is not the only signifier. Different historical powers (belonging to three different empires – Habsburg, Ottoman, and Russian Tsars), geographical and economic differences, large disparities between urban and rural areas, religious influences (Roman Catholic, Orthodox, Muslim), multiethnic territories, and relations between ethnic groups, influence everyday life among Eastern Europe's diverse populations.

After the change in political regimes, the 'iron continent' became fragmented through ethnic wars, massive economic crises, migration, and state-building ventures among the former Soviet Union and Yugoslav Republics alongside international political players (the World bank, International Monetary Fund, and European Union institutions), which influenced economic lives and social policy/legislation of the countries in the region. The area acquired different names according to geographic, economic, or social specificities or international interests (Central Europe, South East Europe, the Balkan region, the countries of the former Soviet Union, and Russia). Some names are historically loaded and negative. The pejorative word 'Balkanization' became used globally to describe phenomena prone to unpredictability, fragmentation, and conflict. Some Eastern European countries were defined as in need of 'Europianization' despite their geographical placement within Europe. Many countries were urged to stop human rights violations of minority peoples if they wanted to become part of the European Union (at least formally). This had some positive impact in democratizing societies and social work (Sasse, 2009). Across the region, a wide specter of different social work practices coexist, varying from very innovative, radical, and liberating ones for persons requiring services and support to oppressive, traditional, and narrow-minded pathology-based responses by professionals and social work institutions.

Social Work's Historical Development before 1991

Despite the belief that social work did not exist in Eastern Europe prior to 1991, there is considerable research showing that professional social work education was established in some countries in the region after World War I, but was disrupted and closed down at the end of the World War II, or soon afterward (Hering and Waaldijk, 2003; Schilde and Schulte, 2005; Hering and Waaldijk, 2006).

At the beginning of the twentieth century, Hungarian, Polish, Romanian, and Bulgarian founders of social work education periodically went hand in hand with the Western counterparts following the idea that social work has to become a profession based on proper education and training – Margit Slachta in Budapest, Helena Radlinska in Warsaw, Princess Ileana in Bucharest, Rayna Petkova in Sofia. They struggled against economic, social, and symbolic inequalities of populations during times of quick and brutal industrialization and deruralization of societies and some fought for the so-called 'woman's question' – women's right to vote, the right for civil marriage and divorce, and more gender equality.

During the period of state socialism, when existing social work training, schools, and institutes were closed down, some communist countries replaced them, e.g., 'social care assistance training' in Romania, 'social nurse' program in Czechoslovakia, and 'social service workers' training in Poland (Iarskaia Smirnova, 2013). For the communist leadership, social work was associated with capitalist ideology, seen as backward, and a counterideology compared with the socialist idea that universal employment would ensure that all other economic, social, and emotional needs of people were addressed by the system of universal social and health protection. Additionally, it was believed that the state as a 'good father'

would protect children, older people, and disabled people through a wide range of long-stay social institutions. Socialism was seemingly able to eradicate the need for social work interventions and ensure the well-being of every 'human being.' Additionally, the omnipotent communist leaders did not allow any innovations except those that came from the Communist Party. One of the first Yugoslav social work teachers who pleaded with the highest Communist Party members to open the school for social work in Slovenia in 1955 expressed their attitude:

> We could write about what happens in the West and about social work abroad, but always in such a way, that it was obvious that ours [Communist Party of Yugoslavia] had written or said that already before them [the Westerners]. We had to be always in front of anyone else (Zaviršek, 2005). (Katja Vodopivec (1917–2012) was a professor of law. In 1958, she wrote the first Yugoslav book on social work methods (in Slovenian language) which was not allowed to be used by social work students and teachers during communism) (Zaviršek, 2005a, 2012)

Yugoslavia was the only communist country that had established schools for social work after the communist take-over compared to 1952 in Croatia, 1955 in Slovenia, 1957 in Macedonia and Serbia, and 1958 in Bosnia and Herzegovina. Today, this is perceived as the unique development of social work education under communism (Zaviršek, 2005a,b, 2008, 2012). This top-down decision making has to be understood contextually, partially as the personal influence of some women Communist Party members who were commended for their commitment during the partisan struggle, were active in the area of welfare protection, and maintained Cold War equilibrium. When the Yugoslav Communists ended their close relationship with Stalin (Cominform split in 1948), they started to cooperate with the United States to avoid political isolation and economic vulnerability (Bilandžić, 1985). Soon afterward, American and Scandinavian advisers became involved in the processes of establishing the first social work curriculum in Croatia in the early 1950s, and social welfare institutions called 'centers for social work' throughout Yugoslavia in the early 1960s. Centers for social work have remained the major welfare institutions in all parts of former Yugoslavia until now.

Social work education also served as a useful way to carry out several goals of the Communist Revolution and partially change the gender order. Social work training ensured education for masses of women and was therefore potentially emancipating. It was simultaneously seen as suitable for retaining traditional femininity and women's 'natural vocation' intact. It created new jobs for women who became employed in large long-stay welfare institutions – nursing homes, boarding schools for disabled children, and asylums for people with disabilities, and was proof that the Communist Party cared about women, especially the peasantry and those from poor rural areas. Large, semiclosed places of welfare state institutions were meant to replace women's unpaid caring work at home. The institutionalization of social work training gave the Party control not only over welfare and gender regimes but also 'in the field,' where 'deviant' behavior such as alcoholism, work hatred, and prostitution could be carefully monitored.

The official definition of the socialist social work was that "social work carries out the goals of social policy" and social workers were primarily expected to work in the areas of social assistance delivery, family protection (which included foster care for children who had lost parents during the war, divorce, and single mothers issues), and to prevent 'deviancies.' Social work education was imposed from above to influence the everyday life of people from below.

From State Socialism toward Neoliberalism

The 'emergency welfare state' (the term used by Tomasz Inglot (2009)) processes after 1991 included new social policy legislation and the development of the mixed system of social services (governmental, nongovernmental organizations (NGOs), and private providers). The times of economic liberalization were harsh for most Eastern European countries and the majority of people (Jäppinen et al., 2011; Bessudnov et al., 2011). The existing industries and state enterprises collapsed and a period of enormous unemployment, among men, women, and ethnic minorities (especially Russians in the Baltic countries, and Roma people in the Czech Republic, Slovakia, Slovenia, Croatia, Romania, Hungary, and Bulgaria) started to dominate everyday life. Poverty expanded and remained the central fact of life. It affected most heavily the rural areas of the region, from where people migrated to capital cities, or from its more eastern parts toward the western parts, and from southern parts toward the north (from central Asia to Russia, from Ukraine to Poland; from Kosovo and Albania to Croatia and Slovenia). In Albania, rates of poverty in rural areas are almost 70% higher than in the capital (Ymeraj, 2007).

People faced many breaks in their everyday routines: privatization of publicly created goods during state socialism (kindergartens, local health centers, factories), flexibilization of labor and consequently unemployment after a long period of full employment, early retirements of a huge number of workers in some countries (Vanhuysse analyzed this phenomenon as the deliberate governmental strategy against the potential resistance toward the neoliberal reforms in Poland and the Czech Republic (2009).), ethnic conflicts and wars, economic migration and the transformation of extended family care systems and family life, the development of huge economic inequalities ('the new rich'), and the return of religious powers as the key political and social players in secularized societies. Eastern European countries moved from state socialism to neoliberalism. Many researchers revealed that international financial institutions heavily influenced national governments' decision making in the economic and social policy areas and worked toward the neoliberalization of the whole region (Deacon et al., 2007).

Violent ethnic conflicts (Croatia, Macedonia), ethnic wars (Armenian, Azerbaijan), and ethnic cleansing and mass killings (Bosnia and Herzegovina, Kosovo), which appeared almost immediately after the fall of Yugoslavia and Soviet Union, caused deaths, disability, forced migration, voluntary and compulsory remigration, increased poverty, transgenerational

loses, and trauma. In Bosnia and Herzegovina, 100 000–300 000 persons were killed and out of a population of 4.4 million, 1 million fled the country between 1992 and 1995 (Maglajlić Holiček and Rašidagić, 2007). Similarly, 850 000 persons fled from Kosovo in 1999 and 360 000 Kosovans sought refuge in neighboring Macedonia, comprising 17% of the whole population of Macedonia (Gerovska Mitev, 2007; Cocozzelli, 2007). After Kosovo proclaimed independence in 2008, social work students disputed whether they are ethnically 'Albanians,' 'Moslems,' or 'Kosovans' and remained divided into three different ethnic identities (personal notes, University of Pristine, 2008).

During state socialism, the nineteenth and twentieth centuries' primordial understandings of the blood–kin relationship based on singular ethnic belonging were replaced by the pragmatic communist ideology, which suppressed ethnic identities to construct a singular, but new identity of a 'socialist proletariat.' After 1991, ethnicity became a 'new' political and social identity for the vast majority of people. This identity was not formally recognized and had not been individually important for almost half the twentieth century. The 'imagined identities' were mobilized by political elites for a new political project of shifting national and state borders. In 1992, the new Slovenian government deprived more than 25 000 persons (official holders of Yugoslav passport who came to Slovenia as economic immigrants) of citizenship rights and erased them from the register of permanent residents of the Republic of Slovenia. They lost all social and political rights and were treated as 'illegal migrants' vulnerable to detention and deportation (Zorn, 2009). In Baltic countries, the exclusion of internal 'others,' e.g., the Russian ethnic minority, helped to construct seemingly ethnically homogeneous states.

Roma people, who are today the largest ethnic minority in Europe, have suffered severely during the past 20 years. There are 9–12 million Roma people in the region, with 2.5 million in Romania. The figures are estimates and include people who have defined their Roma ethnic belongings during National Censuses and those who have not (mostly because of racism). Roma men have lost their jobs due to closures of heavy industry and poor education. Additionally, they have lost alternative sources of earning (e.g., iron, collecting plastic bottles, simple craft, and music) and remained largely without income, and dependent on social assistance money. Many Roma fled ethnic wars. In Kosovo, for instance, Roma villages were burnt after the war, as the local population defined Roma as Serb collaborators. Many of them became asylum seekers, illegal migrants, and long-term homeless. Unemployment levels among Roma people in all countries of Eastern Europe are extremely high, currently ranging from 60 to 90%. Roma women are transgenerationally marginalized, living mostly in segregated settlements that they barely leave. They are unemployed, sometimes illiterate, but receive welfare assistance if they have children. Regardless of the size of Roma populations, all Eastern European countries articulate nationalist rhetoric against Roma peoples ranging from moderate to extreme, some ethnically motivated hate speech, and violent attacks against Roma settlements (Vermeersch and Ram, 2009). This ethnic hatred is the product of a long history of exclusion in the precommunist period, during communism (when Roma people lacked long-term industrial employment and were categorized in the lowest class among socialist citizens, called the lumpenproletariat), and today.

Economic crises and neoliberal transformations in national governments made thousands of people migrate to Western countries to seek jobs and support those who stayed in their country of origins with remittances. In Albania, of 3.1 million people, a quarter (mainly young men) left the country between 1990 and 2005 for Greece and Italy (Ymeraj, 2007). Thousands of women from Ukraine and Lithuania have become care workers, comprising part of the phenomena known as 'global motherhood' (Ehrenreich and Hochschield, 2003). They care for the family of their employers abroad while providing economic care for their families, especially their children, at home. In Germany alone, there are 200 000 female care workers from Eastern Europe with more than 30 000 from Lithuania. In the Ukraine, some estimates show, that in every third family at least one woman member is a migrant worker abroad (Tolstokorova, 2010).

Remittances from Eastern European emigrants have become either a crucial income source or the only family income that helps numerous families to survive. These are therefore desired by governmental officials. Only recently has large-scale migration by women become a governmental concern. In Lithuania, the mass media speak about the 'national epidemic,' while in Ukraine, social workers and other social service professionals speak about the 'Italian syndrome' (abandoned and lonely children receiving monthly incomes from their mothers working mainly in Italy). Some creative responses by social workers were developed to support children who are left alone, e.g., Lithuania introduced temporary guardianship for grandparents who care for children of migrant workers (Malinauskas, 2011). Not only relatives but also friends, neighbors, and school teachers provide social parenting for these children. Social parenthood has become a reality for a growing number of adults and children (Zaviršek, 2009b).

Nevertheless, many researchers express concern that in poorer Eastern European countries, the system of home care is entirely based on the unpaid care work of family members, mostly women, who are today leaving home to seek paid care work abroad (Prochazkova and Schmid, 2009). Older people who are left alone can afford to pay neither state-run nursing homes nor even more expensive private ones. In some countries, social workers are involved in poorly paid community-based home assistance services for the elderly.

Post-1991 Social Work Practice in Eastern European Countries

After 1991, new approaches in social work practice focused on individual and family counseling, the development of community-based services that aimed to replace large long-stay state institutions (especially regarding the care of 'social orphans'), foster care that aimed to replace the system of orphanages, international adoptions, violence against women and women's shelters, crises centers for children, day centers for people with disabilities, and activities linked to 'social inclusion.' For service users, 'social inclusion' was the consequence of early exclusion on the basis of

medical diagnosis seeing intellectual disability, mental health diagnosis, ethnic belonging (identity) as pathology, and early long-stay institutionalization (sending children into boarding school far away from home). Economic, social, and symbolic exclusions created by social workers, health professionals, and pedagogues have been followed by the welfare processes of 'social inclusion' involving the same professionals. Roma children, for instance, who had been labeled as intellectually disabled and sent to special schools across the region, have recently become welfare objects of 'social inclusion.' Not only the countries that became part of the European Union but also other states from the region have adopted modern legislation and policies that have foreseen social inclusion, community services, and deinstitutionalization, but lack implementation. The majority of countries signed and ratified the UN Convention of the Rights of People with Disabilities but in countries in Central Asia, activities for people with disabilities are almost entirely supported by international NGOs and done by the mothers of the persons with disabilities (Zaviršek, personal notes, September 2012, Bishkek; Rasell and Iarskaia-Smirnova, 2013).

The delivery of social assistance money to people who are unemployed, poor families, ethnic minorities, elders, and persons with disabilities is a main part of social workers' activities. In wealthier countries in the region with a wide range of long-stay governmental institutions and community-based welfare services (day centers for people with multiple diagnosis, sheltered workshops, crises centers for children in need, family helpers system, women refuges, and group homes for people with mental health problems and other disabilities) social workers provide placements to these institutions and organize payment contracts usually covered by local municipalities, the state, and the person and his or her relatives. Most of the welfare facilities are located in cities and people from rural areas have difficulties accessing them or must send relatives far away from home to long-stay institutions. The 2008 economic crises caused by international financial organizations forced radical cuts in social protection. Consequently, even more social work activities are focused on social transfer delivery, while community development activities have diminished.

Many types of welfare organizations, styles of work, and approaches have remained the same until the present, for example, long-stay institutions for disabled people despite pilot projects on deinstitutionalization, the denial of most legal and actual rights of children and adults with intellectual disabilities, the nonexistence of independent advocacy work, the denial of self-determination of service users, and the absence of social action approaches in deprived communities. Several conceptual fallacies persist. Many professionals see violence against women in the private sphere as individual pathology instead of structural inequality, welfare systems prioritize closed adoptions for the 'child's own good' instead of open ones, and many children and adults with disabilities are considered well protected in segregated boarding schools.

Social workers from governmental welfare services avoid any form of community action in Roma settlements, and the relationship between Roma and social workers remains highly conflictual (social workers take children into foster care, give conditional social transfer money, and blame mothers for not sending children to school). Local and international NGOs usually work in Roma settlements, mostly organizing different projects with children. Women's empowerment work and awareness-raising on how to protect themselves from violent men are sometimes undertaken by local and international NGOs, but the area remains highly contested. Discussions about child maltreatment and early marriages of Roma girls are avoided and silenced. A small number of *gojim* social workers have developed a strong trusting relationship with Roma men to tackle issues of violence against women and children. There are innovative projects in Bulgaria and Romania, where international NGOs together with social work students and local people set up Roma cooperatives in their settlements.

Local and international NGOs cover many different social work areas. Some social work innovations were only possible with the use of the international money, for example, violence against women, support for rape victims, the development of personal assistance projects and independent living for persons with severe disabilities, deinstitutionalization initiatives, cooperatives for people with long-term mental health problems, support services for mothers with children with impairments, counseling for stigmatized people living in the same-sex partnerships and transgendered people, medical aid and counseling for people affected with human immunodeficiency virus and acquired immunodeficiency syndrome. In Belarus, disability activists try to make the government sign the UN Convention of the Rights of People with Disabilities and a well-known organization for the prevention of women's slavery, *La Strada*, works against the trafficking of women and children across the borders of Russia, Belarus, and Ukraine.

The overrepresentation of the international NGOs had negative impacts too. A joke known across the region during the 1990s has addressed the phenomena: an Eastern European family consists of a mother, father, siblings, grandparents, aunts and uncles, and a local NGO! A common critique against international NGOs was that they dictated the topics of concern and ignored the context and needs of local populations, creating a 'project culture' instead of needs-based provisions (Arandarenko and Golicin, 2007). In some of the poorest countries in the region, international NGOs locally distributed food and other goods to people in need, which established them as the main players among people. A director of a state center for social work from Kosovo recalled: "They had the money to help people, and we didn't have anything to distribute. Then we lost even more credibility" (Zaviršek, personal interview, May 2009, Pristine).

Economic hardship has been experienced by social workers too, and poor salaries have pushed many out of the field (especially from local NGOs). There is no research about the impact of this situation on the quality of social work practice, but some personal stories of social workers show that they individually identify with their clients. A Kosovan social worker who has worked at the center for social work for 30 years has shared this personal story: "My son woke me up in the morning asking me for the money to buy bus tickets. I told him I couldn't give him the money as I didn't have it. Then I thought to myself that I became 'a social assistance case'. I made myself ready to go to work, went to the center for social work where

the clients already waited for me" (Zaviršek, personal interview, May 2008, Pristine.).

In the past decade, all countries of Eastern Europe started to promote market principles in social welfare, especially in the area of nursing homes for older people, sheltered workshops for people with intellectual disabilities, and individual counseling for private customers. The economic crises hit this area of welfare provision too. Private welfare businesses today seek opportunities in areas with cheap labor (establishment of older people's homes in eastern parts of the region for people from its western parts). Recently in Slovenia, older people and their relatives cannot afford to pay expensive residential care anymore, and long waiting lists to enter long-stay private institutions dwindled as facilities emptied. In one of the older people's home, staff went on strike because they had not received their salaries for months.

The Academization of Social Work and Social Work Networks

In 1988, the European Association of the Schools of Social Work conference was held in an Eastern European country for the first time. An anecdote from that conference manifests the *Zeitgeist* and differences between East and West:

> Coming from the West to the conference held by a socialist country, we expected to share with you our new enthusiasm about community work and collective action instead of focusing predominantly on the individual person. But the Yugoslav social work teachers were all against those ideas. We said, "The community work is the right thing to do!" And they said, "No, the work with individuals is what shall be done in social work." (personal communication, 2007)

For Yugoslav social work teachers who were forced to prioritize the community over the individual, the shift toward more individualistic approaches in social work was seen to be something radical and unwanted by the Communist regime. For the colleagues from the West, the turn toward the collective was a radical move, given their individualistically oriented societies that prioritized the individual above the collective, so community action was a more important shift for their social work theory and practice.

After 1991, all countries of Eastern Europe, with the exception of Turkmenistan, established social work education, mainly as a 4- or 5-year university program. The country with the largest number of social work undergraduate programs is the Russian Federation (175 social work departments), followed by Ukraine (50 social work programs), Kazakhstan (22 social work departments), Czech Republic (15 programs), Azerbaijan and Kyrgyzstan (seven universities where social work has been taught), and Romania (four universities) (Iarskaia Smirnova, 2013). The universities with social work programs that have been developed lately are in Montenegro (2003), Uzbekistan (2004), Moldavia (2007), and Kosovo (2012). After 2000, intensive development in postgraduate master-level studies appeared and intensive international collaboration in teaching and student exchanges took place. The processes of the academization of social work are seen in research and the establishment of doctoral studies in social work already in Armenia, the Czech Republic, Estonia, Georgia, Romania, and Slovenia. A cross-national collaboration is also shown in the first international doctoral program in social work and social policy (Indosow) from 2009, which is run by a consortium of the schools of social work from Eastern and Western Europe and was initiated by an Eastern European school of social work (Zaviršek, 2009a).

Today, most of the countries have national associations of social workers and some of them, like the Czech Republic, also have an association of social work educators (since 2009). Social work academics have been active in establishing a number of academic journals mostly in local languages (*The Journal of Social Policy Studies*, Saratov University; *Social Work*, University of Ljubljana, est. in 1962; *Social Policy and Social Work*, University of Belgrade, est. in 1971). Some of the journals contain a mixture of local and foreign languages (*Social Work Review*, University of Bucharest; *Social Work Yearbook*, University of Zagreb), while some are published in English only (*Social Work in Transition*, Kiev Mohyla and Sheffield Hallam Universities). (Only to mention few of them, although almost all countries in the region have academic social work and social policy journals.) In 2008, the schools of social work from the region have established the East European Sub-Regional Association of the Schools of Social Work, which is a large network of social work scholars from the region.

One disturbing characteristic of university-based social work education in some countries is the high number of social work students who enroll because they lack employment opportunities. The quantity of students threatens the quality of social work education. Some social work programs have become hybrid academic–welfare institutions that 'care' for young people and keep them 'in the system' until the age of 25 years or more. Many students seek motherly care instead of academic training from predominantly female members of the academic staff. The University of Sarajevo is a blatant example, but not the only one. Its Social Work Department enrolls 500 undergraduates yearly. They are taught and supervised by 11 academic staff employed in the department. One of the social work teachers bitterly complained: "The government is buying itself social peace while offering 500 social work students' placements at the university!" (Zaviršek, personal notes, March 2013, Sarajevo).

Social work programs across the region lack critical theorizing, historical perspectives, and an engaged community-based and advocacy-oriented practice, which would give students an understanding about differences, diversity, equality, and rights. The area of antioppressive practice is one of the most underdeveloped areas in social work across Eastern Europe. Even when social work students are taught to be critical about governmental social policy regimes and advocate for service users, when they become employed, most of their critical knowledge gets forgotten. This makes a huge gap between social work education and practice. Critical social workers often seek employment in NGOs (local or international), to avoid administrative social work in state welfare services. Lessening the divide between critical social work education and a grim social work practice as well as a thoroughly evaluated practice by the state are future challenges for social workers in the region. Nevertheless,

some social work teachers have worked hard to establish social work training as a social science discipline.

A parallel process alongside the academization of social work is practicing social work as a charity activity and without academic education following the revival of the religious social services. Church power has been reestablished economically after countries returned some (or as in Slovenia, even all) of its confiscated property from precommunist times. With increased neoliberalization, the state's abandonment of social assistance money, housing, and other forms of support for people in need, the church became involved in social welfare work by 'serving the poor.' At the same time, religious authorities became front-runners in morally driven debates against same-sex partnerships, condemning the equal rights of children from rainbow families and promoting increased births among ethnic majority women while enjoying the silent support of different governments. While professional social work has hardly established its moral authority as a human rights profession based on universal human rights documents, religious organizations have built their authority according to an ahistorical natural moral law and its ideological impact is growing.

In conclusion, these developments demand a strong critical social work presence in the region. Social workers who respect universal human rights for service users and support the individual needs of diverse populations to improve the lives of communities can help bring Eastern Europe from its grim history between the 'iron curtain' and neoliberalism toward a more democratic region where individual needs and rights are respected.

Social Work in Organizations

Mark Lymbery, School of Sociology and Social Policy, University of Nottingham, Nottingham, UK

Abstract

Much literature on social work focuses on practice with service users; relatively little attention is given to the need for practitioners to be able to function well in the organizational context. This article will explore the nature of organizations within which social workers are employed, taking the view that many problems experienced by practitioners can be traced back to failures of understanding their place in the world of employment. While social workers are accountable both to the profession and to the service user, the accountability that they have to employing organizations also must be accepted. Using examples drawn predominantly from the British context, the article will first focus on the changes that have occurred within organizations. From this understanding it will then discuss the various ways in which social workers might experience organizational difficulties, suggesting ways in which such problems can be managed. It will conclude by suggesting that effective social work is impossible without clarity and understanding about how the organizational context can best be managed.

Introduction

Most social work discourse focuses on the interaction between the practitioner and the service user, hence, relatively little attention has been given to the organizational context within which the social worker practices. Social workers are rarely autonomous; they work within organizations that impact strongly on each individual's work. In light of this, one cannot examine their practice without considering the context within which it is carried out (Howe, 1991). Indeed, it is the contention of this article that many social workers struggle to come to terms with the demands of the organization after qualifying (Bissell, 2012). In large measure, this can be attributed to a lack of understanding of how such bodies are structured and function, and what constraints this places on individual autonomy. Consequently, it is important for practitioners to reflect critically on the organizations within which they practice. After all, it is pointless to be an excellent practical social worker if the structures within which she or he operates is barely understood.

To address this lack of understanding, the author first charts the development of social work, as this is a central element of any debate about how the organization affects practice. From this, the article will explore the way that discussions about social work often fail to encompass the impact of its organizational location, preferring to present it as a freestanding activity without reference to either its purpose or its setting. This point will be illustrated with reference to the impact of specific changes that have been visited upon social workers in the British context. It will then argue that an understanding of these changes may help practitioners to manage the organizational context of their work more effectively. While the examples in this article are derived from Britain, they are intended to help make an argument that has resonance more widely: that the organizational arrangements that govern social work materially affect the work that practitioners are able to carry out.

The Development of Organizational Structures for Social Work

In Britain, as many histories make clear (e.g., Jordan, 1984), the origins of social work were tied into the sense of charity, and the obligations of the middle class toward people who were less economically fortunate (Harris, 2008). While this was expressed in different ways – the Charity Organization Society (COS) and the Settlement Movement espousing markedly different approaches to the 'problems' of late Victorian society (Harris, 2008) – it was animated by common core principles, Christianity and humanism being the most important. In addition, as the appellation of the COS makes clear, this period also represented a significant organizational formation for social work. The early growth of social work in Britain was later buttressed by university-level education, as both the COS and the Settlement Movement established close working relationships with universities (Jordan, 1984).

In this context, it is particularly significant that the founders of both the COS and the Settlement Movement shared a sense that social work had a 'mission' to fulfill within society – a term that connects to the religious underpinnings of the profession. Despite the differences between the two approaches to the profession, they shared a belief that society could be shaped through the activities of social workers. A core purpose of social work education was therefore to shape the characters and attitudes of those people charged with this responsibility (Dominelli, 1997). As social work progressed into the twentieth century, the sense of mission faded, marking a time when social work became less of a project focused on social change and more a function of society and the state (Payne, 2006). This process was intensified by the formation of statutory children's and welfare departments following legislation in the 1940s: the creation of unified local authority Social Services Departments following the Local Authority Social Services Act 1970 represented the apogee of the growth of British social work as a state-focused profession. Indeed, the substantial

increases in budgets during the early 1970s led directly to a growth in demand for qualified practitioners: consequently, this was a period of optimism for social work.

However, this only lasted for a few years, due to the desperate economic circumstances that consumed the British government during the mid-1970s. The worldwide recession created a particular economic climate for all publicly funded services; this clearly has similarities to the position of social work in the twenty-first century (Dominelli, 2010). If the 1970s is examined first, the decline of British industrial performance led to sharply increased unemployment. In turn, this brought about a substantial growth in public expenditure, balanced by markedly higher taxation. As a consequence of the problem that this created for the public finances, the Labor government was forced to seek a loan from the International Monetary Fund in 1976. In another echo of the disruption caused across the globe in recent years, the terms of the loan required the government to pursue deflationary policies and cut public expenditure (*see* Neoliberalism).

At this point, the modern organizational formation for social work in Britain can be said to shift in its balance and structure: subsequent implications have been both deep and long-lasting. There have been clear manifestations of this. For example, there has been an insertion of market principles into social services work, which has occurred in more countries than just Britain (Dominelli, 2010). This is particularly evident in adult social care following the implementation of Britain's National Health Service and Community Care Act 1990, which simultaneously combined market principles and a consumerist ideology alongside a valorization of the notion of competition (Rose, 1999). The influence of the Audit Commission on the delivery of services in Britain was substantial, emphasizing the disciplines of 'economy, efficiency, and effectiveness,' and securing the consent of local authorities to these particular determinants of their service (Kelly, 2003). This led to the breakdown of the old-established 'welfare bureaucracies' and the development of hybrid organizational forms in their wake (Billis, 2010). At the same time, budgets failed to keep pace with the increasing scale of needs, a problem that was exacerbated by the changing demographics of the British population.

Following the 2010 general election, there was another significant moment in the structure of politics in Britain. When no single party secured sufficient parliamentary seats to form a majority, a coalition government was formed between the Conservative and Liberal parties, with the Conservatives numerically dominant. In its response to the financial crisis that consumed the world economy at the time, the coalition announced a plan to slash the deficit by imposing substantial cuts to public spending, accompanied by some limited increases in taxation. The scale of these cuts was enormous and – in the eyes of some at least – unachievable (Taylor-Gooby, 2012). In addition, they have had a disproportionate impact upon local government, which is the site of much social care provision and the primary employer of social workers.

As can be seen in this brief survey of the organizational changes to have affected social work in Britain over the past few decades, numerous ideological and practical shifts have been observed. In a future section, the author will chart their significant impact upon social work. Before entering into these debates, however, the author will explore the failure to consider the influence of employing organizations in considerations of social work, which tends to promote the decontextualization of social work practice.

The Nature of Social Work

A convenient starting point for a consideration of this rests in the international definition:

> The social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilizing theories of human behaviour and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work.
>
> IFSW/IASSW, 2000

The core problem with any international definition is that it has to apply globally, irrespective of any differences between countries. Partly as a consequence, the scope of the definition is broad. Significantly, in relation to this argument, there is no mention of the organizational context of social work because this is left to local practitioners to define (Sewpaul and Jones, 2004). However, the final sentence contains an element that many social workers employed within statutory agencies in Britain and likely elsewhere would find problematic: the idea that their work is actually (apart from notionally) governed by principles of social justice. In addition, such practitioners might struggle to see their work as being about 'liberation.'

Debates about the nature of social work have tended to focus on its essential purpose. This has been apparent at a number of different stages in social work's development. A particularly clear account of this could be found in the 1950s, by comparing the positions held by Eileen Younghusband and Barbara Wootton (Harris, 2008; Wilson et al., 2011). Largely as a result of what Harris (2008) has termed as the 'psychiatric deluge,' social work theory – if not actual practice – was dominated by psychological approaches: it was this position that Younghusband represented. She held that social workers required deep knowledge of individuals in order to provide them with support, and that it was appropriate for them to look beneath the surface of the 'presenting problem.' This guidance was framed in an ambitious and arguably unrealistic fashion (Wilson et al., 2011), appearing to downplay the relatively small practical things that social workers could achieve, while also underestimating the impact of structurally caused social disadvantage (Dominelli, 1997).

This position was challenged by Wootton (1959), who advanced a more modest role for social workers, suggesting that they should rediscover the core focus of the early pioneers, the relief of poverty. From this perspective, she argued that practitioners could become as essential to the workings of society "as is lubrication to the running of an engine" (Wootton, 1959: p. 297). She also observed that much statutory social work practice was more in accordance with her ideas than those of Younghusband, and hence, that they fitted the organizational priorities of the time. Even in agencies that held more to the values and principles espoused by Younghusband, there later emerged a range of concerns expressed by service

users that seemed to confirm the arguments of Wootton: service users wanted their immediate problems to be resolved before deeper exploration ensued (Mayer and Timms, 1970). However, there remain limitations in her analysis. For example, unless *all* the problems encountered by individuals, families, and communities are held to be the product of poverty, understandings drawn from numerous disciplines including psychology and psychiatry would help people manage their lives (Wilson et al., 2011). There are some problems, e.g., mental health and child abuse, to which the depth of analysis espoused by Younghusband would be better suited.

However, the more modest interpretation of Wootton meant that the organizational location of practitioners became particularly significant. If social workers were to become an essential element in the structure of society, they needed to be operating in some way that linked them directly to the state. This occurred immediately after the Second World War when increasing numbers of British social workers were employed within local government and what they did emphasized the small-scale practical elements of practice highlighted by Wootton. The notion of 'state social work' (Harris, 2008) derives from this change, as the location of increasing numbers of social workers within statutory organizations affected the content of practice as well as its location.

The development of radical alternatives to social work sharpened the debate substantially. Numerous writers challenged the status quo, excoriating social work for its adherence to individual psychology and its parallel sequestration of structural issues (Bailey and Brake, 1975). They sought to develop a theory of social work based on a desire to change the social circumstances within which social workers and service users interacted, an explicitly 'transformational' (Payne, 2006) approach to practice. The core aim of this movement – as outlined in the Case Con Manifesto – highlights these broader goals: "The problems faced by social workers derive from the capitalist structure of society and the place of welfare within it: effective practice must stem from an understanding of how the welfare state has developed, and the pressures to which it is subject" (Case Con Manifesto, 1975: p. 144). Consequently, the radical social work movement saw its primary goal as changing the essential nature of the society within which social work was practiced, and social work had a role in its realization.

However, the movement struggled to overcome a core contradiction: it effectively pointed out the failings of the system, but could not define precisely what radical social workers should do in response to them. In particular, the organizational location of the majority of practitioners within the state created an overwhelming problem. While the radical social work agenda appeared to assume that practitioners had an unlimited capacity to challenge and change policy, this was highly unrealistic: employers were unlikely to encourage their staff to practice in overtly revolutionary ways. Due to the continued location of most British social workers within the state, this remains a core problem, and emphasizes the point that any consideration of the nature of social work has to consider the organizational context through which it is mediated. Radical social workers were aware of this dilemma and wrote *In and Against the State*, setting out the issues and potential responses (LEWERG, 1980), but did not materially change the situation.

This contradictory point at the heart of the profession is not changed by the more recent debates about the nature of social work, of which the exchange between Ferguson and Garrett is a particularly good example (Ferguson, 2001; Garrett, 2003). Here, the distinction is held to be between social work as an exercise in 'life politics' (Ferguson) or 'emancipatory politics' (Garrett). While its scope is ambitious, the idea of 'life politics' focuses attention closely on the individual and the social work role to help maximize her or his life chances. By contrast, the ideal of 'emancipatory politics' is to change the nature of society, and for individuals' lives to be improved through this collective action. Although the terms of reference of this debate have developed substantially, at base there remains a question about whether social work should be relatively modest in its ambitions, focused on improving the life chances of the individual, or whether or not it should have a broader vision and aim to do both (Dominelli, 2010).

As a result of this ongoing tension, Jordan's important question has a particular purchase (1984: p. 13):

> Is becoming a social worker primarily to be understood in terms of the 'helping', 'caring' or therapeutic content of the job, or according to the official, bureaucratic, legal and even potentially coercive powers and responsibilities it entails?

In relation to previous arguments, therefore, the nature of social work derives from a sense of what its purposes might be. Simply put, all the elements that Jordan cites are central to what a social worker might be required to do within the British context, and the organizational location of the practitioner is an important determinant of this. In Britain, many social workers operate in the field of child protection – performing a range of legally derived actions on behalf of organizations. While this should take place in the context of a caring approach, the organizationally defined requirements are clear, dictating the precise actions to be performed. Consequently, this substantiates Howe's point (Howe, 1991): the content and nature of social work needs to be understood by reference to the bodies within which practice occurs. As a result, any changes to organizational structures and priorities have a direct bearing on what practitioners have to do.

Organizational Change: The Impact upon Practitioners

It is important briefly to consider the major political and social changes to have affected the work of social workers in recent years. As before, the author makes specific reference to organizations within the British context, yet the arguments have an inevitably international focus, particularly where they address global phenomena. In this respect, the crisis of the mid-1970s exemplified this: a problem with the worldwide supply of oil and its pricing promoted a global recession. As often happens in such circumstances, public financing is directly affected. The contemporary response to the 2008 recession typifies this response: cuts in publicly funded services. However, striking differences with the 1970s were high levels of political turmoil; unemployment rose sharply and became a major factor in the

1979 election. Largely as a consequence of this, the Conservative Party was elected in 1979, and instituted a set of distinctive political prescriptions for the problems of society. These drew upon a combination of neoliberal economic ideas and neoconservative views about the role of the state and state institutions such as social work (Lymbery, 2004).

These changes had a direct effect on social welfare in numerous ways, particularly in reaction to neoliberal economics. Public welfare was held to be a burden on economic vitality and hence should be reduced in size; as a consequence, budgets failed to keep pace with needs – which were mushrooming as a result both of demographic change and the increase of social deprivation (Ferguson and Woodward, 2009). The supposed 'disciplines' of the market were applied wholesale to areas of welfare provision. For example, the principle of competition underpinned the implementation of community care in the 1990s and heralded the rapid growth of private (and, to a smaller extent, voluntary) sector organizations; this hastened the breakdown of the large bureaucracies that had characterized the growth of the welfare state (Dominelli, 2010). In addition, as has been previously noted, the establishment of the Audit Commission had a major effect on how local government (within which social work organizations were largely based) carried out its duties (Kelly, 2003).

When a Labor government was elected in 1997 it did not materially change the direction of policy. In order to impose a sense of order on these changes, they were collapsed into the single overarching concept of 'modernization,' even though there were often few linking factors to connect them (Harris and White, 2009). While there was a lack of clarity about what the changes meant for social work, there was also substantial continuity with past policies. In particular, many social care services continued to be opened to competition; consequently, there has been a substantial residualization of the social work role (Ferguson and Woodward, 2009). The breakdown of 'welfare bureaucracies' in England (although not in the other British countries) was hastened by the organizational separation of adult social care and children's services following the recommendations of the inquiry following the death of Victoria Climbié (Laming, 2003).

Society has also experienced many changes since 1979. There have been rapidly increasing levels of social inequality, with a consequent growth in the numbers of people experiencing inordinately high levels of poverty. This is significant for social work as it has long been acknowledged that "the most striking characteristic that clients of social services have in common are poverty and deprivation" (Schorr, 1992: p. 8). Therefore, any growth in the numbers of people experiencing poverty has increased the pressure on social services organizations. At the same time, population structures have been changing; a combination of stable birth rates and increased life expectancy will ensure a substantial number of older dependents by the middle of this century, leading to increased demands on social services, while budgets are already struggling to keep pace with need. Additionally, there has been an increased significance of social movements, acting on behalf of people in marginalized groups – e.g., black people, women, disabled people, gays and lesbians, that share a sense of social work being irrelevant to their needs (Lymbery, 2004).

While responding to needs with reduced resources has represented a difficult balance for social work to maintain, it was not effectively challenged throughout the early years of the twenty-first century, boosted by a buoyant economic performance. Where challenges have been presented (Ferguson and Woodward, 2009; Dominelli, 2010) they have foundered on a number of factors: the lack of a strong professional voice and the absence of political champions being the most important. However, the problems did not disappear, and were sharply magnified in 2008, as the risky behavior of various banks caused the entire Western economy to slide into recession. The British government responded in specific ways to this. First, enormous sums of money were found to 'bail out' the banking system, on the basis that the economic structure of Western world needed to be protected (Taylor-Gooby, 2012). At a stroke, this increased the level of the country's debt and the so-called 'structural deficit,' now presumed to have created the crisis (Fontana and Sawyer, 2011). Second, when the Conservative-led Coalition took office in 2010, it established a stringent austerity program to 'resolve' these economic problems (Taylor-Gooby, 2012). A major feature of its approach to the problem was an attempt to convince the country that the primary justification for the need for austerity was the profligate nature of the previous administration rather than the risky behavior of the banks (Clarke and Newman, 2012). In a direct connection with the past, it also perpetuated a sense that the poor were substantially to blame for the problems that transpired – a logic that was common in the nineteenth century (Harris, 2008). It also appealed to the prudent householder on the basis that such levels of debt were apparently outrageous – in effect applying microeconomic logic to a macroeconomic problem. In addition, the way of resolving the problem was by massive (and never before achieved) cuts in welfare expenditure (Taylor-Gooby, 2012); in accordance with the original austerity plan, it was proposed that £110.3 billion would be found to manage the problem of public debt within one parliament, of which 73% would be cuts to public expenditure and 27% to taxation (Taylor-Gooby, 2012).

Because the nature of social work is primarily to serve people who are both disadvantaged and poor, the implementation of this austerity package is likely to affect the poorest most deeply, despite the rhetorical commitment to fairness voiced by the coalition. Certainly, the proposed 27% cut in local government expenditure between 2010 and 2015 will have a particular impact on social care and social work. It is consequently important to develop a sense of how practitioners can be enabled to manage the organizational changes that are in train: this is the focus of the following section.

Managing the Organization

Given the problems identified in the previous section, social workers have two tasks to fulfill. The first problem is pragmatic in nature: how to survive and prosper in such difficult environments. The second is much more fundamental and perhaps impossible for a social worker to accomplish in isolation: how to change the nature of employing organizations such that they become more attuned to wider social upheavals and more

supportive as contexts within which to practice. This section will primarily engage with issues that connect to the first problem. Issues that derive from the second will be addressed in the conclusion.

There are several key consequences for the practice of social work that have to be acknowledged and worked with effectively. For example, the pressure on resources will lead a practitioner into difficult terrain as she or he will inevitably get into areas of conflict. To use Thomas's own terminology (1992) austerity measures are affecting the 'structural' context within which the 'processes' of conflict management are played out. Along with a colleague, Thomas developed a two-dimensional taxonomy of conflict handling modes, the Thomas–Kilmann grid (Thomas, 1992). In this taxonomy, the five modes of conflict management (competing, collaborating, compromising, avoiding, and accommodating) are classified in relation to two underlying dimensions, assertiveness and cooperativeness. As Sportsman and Hamilton (2007) have indicated, the 'behavioral predispositions' of most human services workers – except medics – tend to ensure that they focus on unassertive and often uncooperative approaches to conflict (avoidance). This is deeply problematic when the outcomes of conflict are so critical for the service user – social workers, therefore, need to have a much more rounded set of approaches to its management. The need for this is magnified when a worker has to balance the difficulty of reconciling the 'partisan' nature of optimizing the outcome for an individual with the ideal of affecting a 'systemic' change for the wider organization (Thomas, 1992). In many cases, these will be in opposition. For a practitioner, the imperative to manage conflict effectively on behalf of the individual or group may bring her or him into direct conflict with the organization, thus putting a premium on the capacity of the worker to operate effectively in conflict.

Another potential consequence of the austerity program lies in the likely increase in the levels of stress experienced by social workers. In social work, these are elevated in normal circumstances (Lloyd et al., 2002); if left to develop, they can contribute to negative outcomes – high levels of staff turnover, dissatisfaction with the job and the nature of practice, and potential burnout (Cherniss, 1995). There appears little doubt that changed economic circumstances have increased the problems of many service users: since it is social workers who operate closely with such people, it is likely that the gap between their espoused ideals and actual practice will widen, increasing the levels of stress that they might experience (Lloyd et al., 2002). The potential negative effects of stress can lead to profoundly damaging experiences, which can include problems in concentrating, depression, and increased levels of sickness – both real or imagined (Cherniss, 1995). The corrosive sense of futility that can develop can also contribute to high levels of emotional distress, leading to a downward spiral within which an individual's performance deteriorates and her or his sense of job satisfaction plummets.

That the job may be experienced as increasingly difficult does not mean that every practitioner will succumb to stress and burnout (Collins, 2008). There is the potential for workers to build appropriate coping strategies to create resilience against the pressures of the role. It is simultaneously important for any individual practitioner to feel that she or he is making a difference to people's lives, while relishing the manifold opportunities for change and variety that present themselves. At the same time, managers need to recognize that there are features of work that help to build a sense of strength and resilience, notably the fostering of appropriate levels of autonomy (Cherniss, 1995). There is clearly a responsibility for managers within organizations to think carefully about the factors that can enhance job satisfaction and reduce stress (Collins, 2008), however difficult that may be in the current climate.

Given these additional pressures Morrison (2007) has suggested that it is particularly important for social workers to be able to demonstrate active levels of 'emotional intelligence,' to be aware of the impact of external events, and to be proactive in managing them. The way in which organizations are structured clearly indicates that they require considerable flexibility on the part of practitioners to manage the tensions and emotions that are produced. Consequently, workers must be able to function effectively within their confines, despite the additional pressures that derive from straitened economic circumstances. This implies a high level both of self-knowledge and awareness of the needs of others, plus a sophisticated ability to manage the context within which the interaction takes place (Morrison, 2007).

Cherniss (1995) has indicated how important this is in relation to avoiding burnout. In his view, professionals – who are particularly prone to burnout – must move beyond the demonstration of 'technical proficiency' and develop both organizational and people skills that will enable them to negotiate through work settings successfully. He termed the aggregation of such abilities as 'organizational negotiation skills,' which include the capacity to avoid or quickly resolve interpersonal conflicts and 'hassles,' which can result in stress and burnout, alongside the ability of not to become distracted from the task at hand, and one's own work goals (Bissell, 2012). In relation to social work in conditions of austerity, the need for this – and its potential benefit – is obvious.

Conclusion

However, enabling practitioners to function more effectively within organizations is only part of the solution. The other rests in finding a way to make them a more sympathetic location for social work. If this is not accomplished, the consequences are potentially dire, but it remains a difficult task to achieve. The first point to assert is that any individual's attempt to do this from inside an organization is likely to end in frustration and failure – it is an activity that calls out for a more sophisticated united response (Ferguson and Woodward, 2009). The need for social workers to rediscover and build upon their collective identities is therefore strong.

The key element in this is the active gathering of support for a particular action or position. If, for example, a worker is concerned about the implications of a particular course of action, it will be more effective to question this in concert with others rather than expressing an individual view that can be readily set aside. Raising an issue collectively avoids the risk that the concern can be taken as one person's gripe and hence easily be marginalized. It is also important to recognize and

understand the nature of decision making within an organization, in order to understand where and how to intervene. If problems are being caused by inadequate or inappropriate decisions taken elsewhere in an organization, it is clearly appropriate to press for change within that context. However, if the problems are caused by decisions over which the organization has no control, effective forms of protest need to be directed toward the location of the specific problem.

The impact of the austerity program is a case in point; it is potentially unhelpful and unproductive to protest to an organization about the overall cutting of budgets where the body has no choice other than to make the cuts. Any protest would need to be constructed more broadly and aimed directly to secure a change in policy. However, decisions that relate to how the cuts are to be implemented are clearly appropriate for protest. If, for example, they result in a disproportionate impact on specific user groups it is right and proper – and arguably a moral obligation – for a social worker to protest against them; in such circumstances, it is also important to consider ways in which such objections can be most effective.

It is apparent, therefore, that consideration of the organizational context for social work practice is far from being an optional extra for practitioners. Rather, coming to grips with the organizational context is vital if they are to develop forms of reflexive and ethical practice (Hughes and Wearing, 2013). Being able to understand and creatively manage the organization is therefore an essential skill for a social worker (Bissell, 2012), without which the effectiveness of her or his practice will inevitably be diminished.

Abstract

This article outlines a range of the general and the unique features of the social work's development in Russia. It explores the historic context of Soviet rule and period of transition, describes the postsocialist development of social services as well as establishment of social work as an occupation in early 1990s, and concludes by tracing general trends in the development of social work.

Introduction

The article consists of five sections. Starting with outlining a brief history of social work in Russia, this article then turns to the main features of welfare developments and beginning of social work as an occupation during the transition from socialism to the democracy and market economy in 1990s and considers the contemporary development of social work as a profession and a training program in today's Russia. The article ends with outlining the core features of governance and professional status of social work. International influences and value clash are touched upon as well as the public understanding of the profession.

A Brief History of Social Work in Russia

Short historic background presents the picture of welfare policy and social work formations during socialism and under the transition. Various forms of social care and social service were developed under Tsarist Russia and during the socialism (Hering, 2009; Iarskaia-Smirnova and Romanov, 2009b; Iarskaia-Smirnova, 2011a; Waaldijk, 2011). As elsewhere, the preprofessional history of social work included religious and civic institutions and activities related with charity and social care. Orthodox, Catholic, Jewish, and Muslim traditions played important role in organization of social care and training for personnel in social services such as shelters for homeless, disabled, and impoverished people, institutions for orphans and poor children. Many such institutions were demolished or reestablished under the state socialism but on different ideological basis. The disciplines of sociology and psychology, as the most solid core for critical thinking and dissent, were eliminated from the university curricula or they were allowed only to follow the line issued in Moscow (Guzzetta, 1995: 192).

In its golden age, relating to the early Khrushchev and Brezhnev periods, the Soviet government built one of the most advanced systems of social assistance in the world, concerning access equality as well as the volume and quality of services (Schilde and Schulte, 2005). And although the right and duty for labor determined the access to many social services directly from the workplace, the segment of a universal welfare regime with typical disposition of domiciliary services available for all district residents was extended as well (Iarskaia-Smirnova and Romanov, 2009a).

As official state policy did not recognize the existence of social problems, a need for social work could not be articulated explicitly. The population not only passively enjoyed the benefits of socialist welfare, but many were actively seeking state welfare and demanded fairness, which led to repressions and elimination of protesters. The state and its various agents played a major role in carrying out the double-edged care-and-control task at all levels of social life. Because of limited resources of the state and following the socialist ideas of self-government and the socializing role of collective, voluntary children workforce was broadly used in providing help to people with disabilities, and the elderly; while issues of women and children, family issues have been dealt with by women's councils and trade union units. They performed the care-and-control functions that were in common with certain forms of professional social work service elsewhere (*see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'; Social Work in China). However, issues of disabilities, mental health, ethnic minorities, and violence against women and children were silenced (see: Waaldijk, 2011).

In the Soviet Union, social assistance and care were provided without the official presence of social work as a profession, which was introduced only in late 1980s–90s. During the 1990s, when Russia underwent the transition from socialism to market economy and democracy, crucial transformations occurred to the role of the state, the ideology of social support, and to the models and instruments of social policy and social services.

Social Welfare under Transition from Socialism

During the 1990s, many of the existing institutions and values were challenged and changed. Free education, public health care, and social benefits that had been a fact of life for decades in the Soviet Union became objects of deep nostalgia and frustration for many people, especially older people.

The economic decline, increase of levels of poverty and unemployment, and extreme lack of resources have tempered the welfare reform throughout the region. High levels of

poverty particularly affected vulnerable groups such as older people and people with disabilities (Standing, 1998).

Having embraced a different shape of economic and political development during socialism, Russia as well as other postsocialist countries (*see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'; Social Work in China) undertook big and various efforts to repair the former welfare states or build them anew (see Cook, 2007). The postsocialist transformation proceeded from 1990. The vector of social reforms has continued to change under the influence of changing national political agendas and international influences.

Russia inherited from the Soviet period a complex system of social security based on public institutions, without professional social work and with the small social transfers to a wide range social groups (people with disabilities, single mothers, veterans, altogether more than 150 categories of population), which were paid irregularly.

The government became aware of the need to develop a system of social services as a part of a modern and professional social welfare system and continued to develop, or started to establish, a new system of social services based on essentially new legislation. Social work was introduced in 1991 as a new occupation and simultaneously as a new university degree program. During the 1990s, many Russian universities established university programs in social work, and in some cases, in social pedagogy, and more recently, in youth work.

In Russia, the persons with a title 'social worker' stated on a badge, first became known to the public during *perestroika*, in late 1980s. It was a time of total shortage of food and goods, when people had been standing in huge queues in the shops in order to buy simple products. 'Social workers' had the right to buy things without waiting in a queue because they were assisting older people and people with disabilities with some domestic chores. A professional of a higher status received in 1991, a separate definition of 'specialist of social work.' Another title for a practitioner with similar qualifications, a 'social pedagogue' was introduced in early 1990s, adopted from the German and Danish models.

During the 1990s, a wide network of social services was established under the responsibility of the Ministry of Labour and Social Development (recently Ministry of Labour and Social Protection). This social services network has been expanding rapidly during the last 20 years. The workforce of social services provides care in many different settings, which according to the Social Service Federal Law (1995) includes home care, social assistance for family and children, social-rehabilitation services for children and youngsters under 18, helping children who are left without parents, shelters for children and adolescents, psychological–pedagogical help to the population, hotline services, night stay hostels, day care for lonely older people, residential social services (nursing homes for elderly and disabled, psycho-neurological nursing homes, nursing homes for children with mental retardation, nursing homes for children with disabilities), and older people's care. Residential care established in state-owned institutions and other state-based social care services are also found in Russia. Outreach work with youth delinquents, drug addicts, and homeless people is conducted mainly by NGOs including religious organization, which are active in big cities.

In the 1990s, a series of new social legislation have been adopted here. Russia as many other postsocialist countries became a member of the Council of Europe, the signatory to the Universal Declaration of Human Rights, and has ratified a number of other international human rights instruments as well as European Social Charter. New institutions had to be built to resume the place in the global international order (*see* Globalization, Welfare, and Social Work). The development of social welfare and social service legislation in Russia as in other postcommunist countries (*see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'; Social Work in China) has been modeled in close collaboration with international and supranational organizations including the World Bank, UNDP, USAID, UNESCO, EU, whose support was welcomed as an important economic and symbolic resource (USAID, 2008) (*see* International Social Work Student Exchanges).

In accordance with neoliberal ideology of reforms (*see* Neoliberalism; New Managerialism and New Public Sector Management), a universalistic approach was considered ineffective, and the emphasis in solving welfare problems was shifted in mid-2000s to a means-tested scheme. As in many other postcommunist countries, with the adaptation of a discourse of poverty, the needs of clients in Russia, too, were reduced to means-tested poverty relief (*see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'; Social Work in China). During the transition from socialism to the market, new surveillance techniques and disciplinary welfare practices were introduced here that pathologized and stigmatized the clients (Haney, 2002: 235).

Social Work in Postsocialist Russia

Under state socialism, the state provided residential care and material assistance for certain categories of population while many problems were to be solved by the families, teachers, police, and formal and informal collective networks. This approach has been challenged as narrow, but such an assumption is still widespread. Social work in the child protection area, deinstitutionalization, juvenile justice, work with disabled children and their families and also with young people are the new areas of research and training as well as practice models. The movement to protect and/or deinstitutionalize children in vulnerable situations is confronted by a weak child protection system and ideological conflict that might increase risks for children.

Assumptions on human rights as well as on role of the state, market, and civil society in social policy and social work can differ and the clash of ideologies is inevitable. One of the examples is presented by the clash between child-centered and family-centered child protection models in case of juvenile justice. Under socialism, juvenile justice did not exist and the policy on punishment has been rather sound (see McAuley and MacDonald, 2007). In 1999, juvenile justice was adapted from foreign experience under a French–Russian project intended to change the system toward preventive approaches and reducing imprisonment among young people. Within a few years, 20 Russian regions had set up juvenile courts with support of the UNDP, UNICEF, and foreign agencies and foundations from

France, Sweden, and other countries with involvement of the Supreme Court of Russian Federation (see Trygged, 2009). From 2005 to 2010, negative public opinion toward juvenile justice was accelerated by moral panics orchestrated by the mass media. In popular protest, various arguments have become mixed-up:

> Juveniles are often presented as a threat for society or as insecure victims who should be protected from careless parents, pedophiles, drugs, etc. The child protection agencies have been sometimes in public discourse named 'juvenile services' and criticized by public as the 'Western' idea of state control over the private life. These claims are formulated by the conservative media, nationalists groups, and by the Church but sometimes it is initiated or supported also by representatives of the government, discrediting juvenile justice. The critics claim that focusing on children's rights undermines an important role of family against Russian traditions. Some publics, social services, ombudsman, and NGOs support juvenile justice, but the national legislation reform on juvenile justice was blocked due to the stigmatization of the idea itself.

Public discourse that frames social work practice contains a mixture of various and often contradictory value positions concerning normative models of good citizens, men and women, families and children (*see* Feminist Research in Social Work). Old prejudices against certain groups have retained from the past (Guzzetta, 1995: 202) not only in Russia. The revival of neoconservative movements is known in many countries of the world, including 'old' and 'new' Europe and ex-Soviet republics (*see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'), where escalation of sexism, homophobia and racism, prejudices against Roma, people with disabilities, and other minorities are seen and experienced (*see* Critical Reflexivity and Social Work Practice; Roma Peoples, Discrimination and Social Work Practice; Critical Social Work Practice). Thus, the wider societal context of social work is constituted by the mixture of ideologies, where neoconservative voices sometimes are interwoven with social democratic and/or neoliberal agenda while "paternalist and authoritarian values of legislators, bureaucrats and even the public" (Freed, 1995: 40) are clashed with the agency of those service users, NGOs, and service providers who tries to criticize and challenge the networks of power (Iarskaia-Smirnova and Romanov, 2012) (*see* Critical Reflexivity and Social Work Practice; Choice, Empowerment, and Social Work).

The development of social work is framed by national and local policy contexts. One of such contextual elements is religion. In Russia, the role of religion in the lives of the people is taking on significant meaning, particularly the role of the Russian Orthodox Church and Islam in the revival of charity, and the role of the religious organization in service provision are gradually growing. It inherits historic traditions of mercy and charity, and volunteer help to the needy, which was widely spread in prerevolutionary Russian society and arranged around the churches and cloisters. During socialism, civil sector and religious organizations have been put under the strict state control. Volunteer movements started to rise again in late-Soviet times in 1980s and especially in postsocialist Russia since early 1990s. Various self-help and mutual aid groups, charity initiatives have been established on different value bases. Many religious organizations of different persuasions developed forms of aid including orphans in institutions, prisoners, homeless people and others in need. Some of them arrange seminars and courses for practitioners. Social work at the parish of Russian Orthodox Church has gradually become professionalized acquiring the common features of this profession. Since 2011, the Church administration has held annual distant learning courses on social service with the possibility of field practice facilitating the study of best practice examples in Moscow. The participants acquire theoretical foundations on casework and state social policy; learn about social work methods, social work organization and management, public relations, practical skills of working with homeless people, prisoners (see Romanov and Kononenko, 2014).

In order to mobilize resources of local communities to help vulnerable groups fully realize their social citizenship, social workers have collaborated with nongovernmental services, including women's organizations, trade unions, and human rights organizations. Some NGOs, which have grown out of service users' associations and grassroots movements, developed a strong emancipatory view in their work. The number of such organizations is limited and unstable due to the economic and political situation in Russia, where involvement of foreign donors is not encouraged while national funds to support nongovernmental activities are scarce (Iarskaia-Smirnova, 2011b).

Social Work Training

The revival of social thought in Russia, supported by national and international foundations, animated public discussion on matters of social inequality, social exclusion, and social problems and through the activities of university departments and independent research and training centers. While in several Central and Eastern European countries, the profession has acquired public recognition, and universities have been developing their programs for several or many years before the 1990s (e.g., Zaviršek, 2008; *see* Social Work in Eastern Europe: Surviving Neoliberalism after the 'Iron Curtain'), social work was a new occupation in Russia and other former Soviet republics.

The first four universities started to teach social work courses in 1991 and by 2011 the number of university programs of social work was about 175 and they covered the entire country. In addition, there are about 115 university programs in social pedagogy. Currently all universities are involved in a process of transformation toward the Bologna system (*see* Bologna Process and Social Work) switching to 4-year BA (established in 1992) and 2-year MA (established in 1996) levels, although some continue to offer traditional 5-year diploma programs of 'specialists in social work' (established in 1991). As an educational program, the Bologna Process was imported here from the West through the efforts of universities, individual scholars, and social work practitioners who became involved into various forms of collaboration, knowledge exchanges, academic mobility, and the establishment of joint degree programs (*see* International Social Work Student Exchanges; Social Work Education).

Opportunities for training and continuing education for practitioners and teachers became and still are available mainly

through international collaboration between foreign universities and practice agencies, the government, social services, and academia. Such schemes have been welcomed, and the projects provided resources for institutional and curriculum development. They also influenced teaching methods and widened opportunities for teachers to improve their qualifications through new cross-cultural communication experiences, and the acquisition of updated professional knowledge (see Iarskaia-Smirnova, 2011b) affected practice models in the projects that have involved governments and social service agencies (*see* International Social Work Student Exchanges; Social Work Education).

Due to the delayed professionalization of social work in Russia, there is a lack of professional knowledge and skills among practitioners. A number of collaborative international projects dealing with social work and welfare developments have been implemented since early 1990s, aiming to raise professional competencies in public authorities, managements, and among social workers in Russia (e.g., Gilbert, 1999; Eduards et al., 2009; Trygged, 2009) (*see* International Social Work Student Exchanges).

Much attention has been paid to adopting of new technologies, standards, and their application into work practice at a local level. Specialists have acquired new models of work; new approaches to social work have been adopted. Social service administrators and practitioners have very positive attitudes to opportunities for professional development whether it is locally based or has origins abroad. However, they have no autonomy to participate in any international or local projects without the permission of regional and/or national authority.

International collaboration induced multifaceted exchanges and influences. A number of strategic international partnerships on all levels of welfare governance and practice have been built (e.g., Trygged and Eriksson, 2009; Doel and Penn, 2007). Local academics have been actively engaged in such cooperative ventures, while governmental agencies and social service administrators have played an important role in opening the gates into the practice fields.

One of the most critical issues for the beginning of educational development in social work during the 1990s was the lack of teachers competent in the subject and lack of teaching materials. Due to the extensive and lengthy suppression of social sciences and psychology during Soviet times, social work textbooks have been inadequate in their critical appraisal of social problems, and preparing social workers for the reality they will face. The principles of nondiscriminatory or multicultural social work, empowerment, and social criticism are rarely present in the textbooks analyzed during 2005–10 (see Iarskaia-Smirnova and Romanov, 2008; and Critical Reflexivity and Social Work Practice; Choice, Empowerment, and Social Work). However, social work literature in Russian language is currently growing, a few translations are being produced, and many original works are published in journals and books by scholars and practitioners in the region.

The students are trained in research skills and given macro-level knowledge on welfare policy and legislation, as well as theoretical knowledge on psychology and theories of social work (Gilbert, 1999: 15). A practice component is still lacking in the curriculum. Formalized internship was, and partly still is, especially difficult (see Iarskaia-Smirnova and Rasell, 2014) to establish when appropriate field placements do not exist (Guzzetta, 1995: 205; see also Montague et al., 2008: 241). Although during 20 years of social work education, placements have been secured, field supervisors are still lacking in those settings where low salaries and the absence of career opportunities prevent employment of university graduates in social work agencies, while social workers with practical experience not necessarily have adequate qualifications (see Penn, 2007; and Social Work Education). The system also has employment problems in labor market for the graduates of such programs. Due to the low salaries offered to qualified social workers, young university graduates are choosing other jobs for themselves. Thus, the vast majority of social workers (or specialists in social work) in Russia still have not received formal education or professional training.

By setting up inadequate wage policies for social workers, the state has reinforced the societal assumption of this occupation as 'cheap women's labor' (Iarskaia-Smirnova and Romanov, 2008). These women "represent a *de facto* voluntarist service. Lacking a clear framework for career development coupled with the prospects of a reasonable standard of living, it is difficult to see how social work as a profession will attract" (Gilbert, 1999: 18) university graduates. The high fluctuation of personnel due to the poor wages, large caseloads, and insufficient training opportunities in many cases has hindered the professional development of social services in Russia.

Governance and Autonomy in Social Work

The top-down approach to solving social problems and regulating the profession is still in place as it was under state socialism. The state has the main jurisdiction over the new profession and provides it with financial and symbolic capital. There is special social services legislation in Russia defining social work in direct terms or as a social service provision. Here, as in some of the Eastern European countries, the concept of care or charity is a priority above the concepts of citizenship, entitlements, and civil rights in social service legislation (Krzyszkowski, 2004/2005). Social work as home assistance for older people is the most typical public understanding of the profession. Although a greater emphasis in education and legislation is placed on nonmonetary social services, "practising social workers find themselves means-testing clients for pensions, providing specialist services, and giving routine institutional and domiciliary care" (Gilbert, 1999: 18).

In the Law on the Foundations of Social Services (1995) the term 'social service workers' is used, while a 'social worker' is defined in the new draft of the Law on the Foundations of Social Services (2013, to be enacted in 2015) as a specialist with professional education relevant to the job functions, who works in any kind of organization that performs social services. The new law formulates the rights, responsibilities, and guarantees of a social worker, in particular, the rights to receive professional training and further qualification training, to form and build professional associations.

Since the beginning of the 1990s, the field of social work practice was developing rather separately from the field of

professional training, while the situation in the human resources of the social work services sector was characterized by low wages, labor shortages, high fluctuation of personnel, and insufficient opportunities of retraining. There is no regulative legislation that requires a formal education in social work for a person wishing to begin professional practice. National standards for social services specify that functions and activities of workers are gradually being adopted but their implementation is a slow process.

In the early 1990s, four professional associations were created: The Association of Social Workers, Association of Social Pedagogues and Social Workers, Association of Social Services Employees, and Association of Schools of Social Work. Also, several magazines on social work were also established. Since 2001, the Union of Social Pedagogues and Social Workers (the Union) has been acting as the national association with over 4500 members in 70 regions of the Russian Federation. It has been active in promoting the prestige of social work and building a national community of social work practitioners, administrators, and educators but was not in possession of a self-regulatory and licensing mandate. The Union publishes a periodical 'Sotsial'naia rabota' (social work). These professional associations have no power as regulatory bodies.

The most characteristic feature of the socialist legacies here is the persistence of the monopolized position of state-based public services and limited possibilities for creating a competitive environment (Romanov, 2008). In Russia, unlike in the USA or Australia, social workers are employed mostly by governmental agencies. Commercial sector is unlikely to develop here in the nearest future (Gilbert, 1999: 10) although the social services market in Russia is slowly developing, with a very few nongovernmental players, such as alternative nonstate providers. The government gradually increases budget allocations for the grants to be distributed among nongovernmental social services hoping that the third sector would grow.

In 2000s, the central government intended to make relationships between the citizens and the state more efficient and effective.

So far, welfare agencies are governed by a highly centralized bureaucracy and one can talk only about relative autonomy of social workers. However, there are some exemplary cases of social workers affecting structural changes (see Iarskaia-Smirnova and Romanov, 2013). For instance, a social worker from a northwest region of Russia has been working in a public agency and at the same time was a leader of the association of NGOs of people with disabilities of the region, taking part in the international projects on social work. In 2004, she supported a court appeal by a group of parents who sought preschool places for their children with disabilities because they had been rejected earlier by the city authority. Collaboration between the parents' movement, NGOs, and social workers with the engagement of the mass media has led to structural changes, such as establishment of personal assistants, reconstruction of facilities, and a new regional legislation, "On providing access to the public buildings and transportation for people with disabilities and other citizens with low mobility." In this case, a practitioner who promoted and was engaged with collective action, was able to enhance her professionalism through international exchange programs.

Since the early 2000s, a reform has gradually taken place by which public social services are being converted into semi-autonomous organizations. The idea is to make public services capable of operating in a quasi-market, without guaranteed financing and to compete for budgeting with other providers. This reform has been launched as an experiment in several regions in early 2000s and recently, the possibility to choose the legal frame (i.e., to choose to become semi-autonomous or continue to be based on a guaranteed budget scheme) has been opened for all social service organizations by Federal Law in 2010. It has made it possible for various types of organizations including nongovernmental services, to participate in market competition.

The competitive nature of a rising social services market is being fostered by the so-called 'contests of social projects' – a competition among various organizations for small grants arranged by the local governments. However, the procedure is characterized by a lack of transparency and lack of clear criteria for evaluation of the proposals and the outcomes. This process is limited by a lack of standards of social services, a weak knowledge base concerning the methods for working with clients, standard regulation in this field, a lack of skills in project management, and inadequate evaluation by many public and NGOs (*see* New Managerialism and New Public Sector Management). It is assumed that management of public services will gradually become more flexible, possibilities for commercial activity will grow, and the wages and motivation of workers will increase as well as opportunities for their professional development. It was expected by the authorities and now is shared by social service managers that the administrators and the staff of autonomous organizations would be more enterprising, acting in more innovatory and entrepreneurial way for the interests of service users and communities. A number of policy actors have been promoting their interests in shaping the legislative, socioeconomic, and political environment for social work, competing for legitimacy and status in policy processes. It is important for the government, national, and international foundations, as well as professional and academic community, to focus more on critical issues in social work both locally and globally (*see* Globalization, Welfare, and Social Work). It is worthwhile paying more attention to retraining programs and raising the level of skills of staff who already work for social service agencies, because the vast majority of staff in those agencies do not get basic training in the field. Education is called to contribute to the development of such reflexive professionals who would be able to recognize inequality on individual and institutional levels in direct contacts with clients or on a structural level during organizational, social, and political interaction and come up with innovative means of tackling these problems.

The importance of improving such training increases due to the intensive growth of social services and the demand for well-qualified personnel. There is a growing need for appropriate professional literature as well as for the popularization of civil society and human rights values by the mass media. An effective mechanism for the independent evaluation of social

services is also needed, to make it possible to target educational and fundraising activities.

Due to a lack of strong professional associations as well as communities of clients, it would be not easy task to define occupational standards and codes of ethics from below. Representatives of academia and the government take the lead in elaboration of the first versions of such documents. In 2013 occupational standards for social work have been elaborated and the code of ethics for the employees of social services has been drafted by the government. The professional associations took part in discussions of these documents. Gradually, social work will be developed and enhanced as a profession and this process would lead to a (re)formulation of qualification and values based on practical experience, national and international expectations, and knowledge in theory and methods of social work, human rights, and dignity. It is worthwhile to pay more attention to retraining programs and to raise the level of skills of staff already working for social service agencies who do not get basic training in the field. It is also important to conduct research of social policy reforms and social work practice in order to discuss the functions, competencies and values in professional community.

Social Work Theory

Barbra Teater, College of Staten Island, City University of New York, NY, USA

Abstract

Social work theories serve as the foundation for social work practice by providing an understanding, explanation, and prediction of human behavior and social structures. Seven general categories of theories used in social work practice are reviewed and their relevance to the stages of social work practice of assessment, intervention, evaluation, and endings are discussed.

Introduction

Social work theories serve as the foundation for social work practice by providing an understanding, explanation, and prediction of human behavior, social structures, and social interactions. Theory informs each stage of the social work process from the initial stages of assessment, to selection and evaluation of interventions, to deciding when it is best to end services with clients. The profession of social work aims to promote social change and social justice by working with people and the environment in which they interact. Intervening within several different layers of society, including individuals, families, communities, and societal and political structures, is necessary to achieve this aim. Therefore, social workers must have a firm understanding of the operations of human behavior, relationships, social interactions, and social and political organizations and structures. Theories provide the necessary knowledge to begin to achieve this aim.

Social Work Theory

A theory is an organized set of assumptions, beliefs, or ideas about particular phenomena in the world. Theory is synonymous with hypothesis, presumption, speculation, belief, idea, and philosophy and is used to help explain or predict situations, actions, and consequences. The social work profession aims to intervene at the point where people meet their environment, which requires social workers to have an understanding of the operations and complexities of working with and within these different systems. Established theories serve as a basis on which to explain human behavior, growth and development, psychological and social functioning, the construction of social order, and the ideas of social justice.

Working within the different layers and multiple systems within society makes social work a unique profession. Social work is a relatively new profession. It originated in the nineteenth century to address the economic inequalities that became more prominent after the end of feudalism and the emergence of the industrial revolution. Social workers aimed to combat the effects of poverty and promote social justice. In doing so, social workers not only needed to work with and understand human behavior, but also understand societal and political structures and the interactions between society and individuals. This need to focus on individuals, and the environment in which they live and interact, required the profession to look to other academic disciplines where established theories of humans, society, and the interaction between the two were already established. Therefore, theories within social work are predominately drawn from other longer standing academic disciplines, such as psychology, sociology, and philosophy.

The Importance and Use of Theory within Social Work

The social work process involves stages of assessment, intervention, evaluation, and endings with an overall goal of promoting human growth and development and social justice (Teater, 2014; Turner, 2011). To initiate each of these stages, social workers must first have an understanding about how best to proceed with each stage given the particular situation, circumstances, and setting in which the practice is taking place. Social workers are working with vulnerable people in situations that are variable. A single approach to social work practice will not fit all. Social workers must tailor their practice to fit the specific needs of the client given her/his circumstances and a consideration of the environment in which the client is interacting. Theory is the critical factor in assisting social workers' understanding of a situation, hypothesizing about how to intervene, and speculating and predicting what might happen in the future (Teater, 2014; Turner, 2011).

Theory guides social work practice at every stage. During the assessment stage, theories help to explain what is happening with a client, what could have contributed to the presenting problem, and what is needed or required to alleviate the problem. A consideration of biological, psychological, and sociological theories during the assessment process assists in explaining the presenting problem and helps to structure and organize the social worker's thinking toward the next step of intervention. The intervention stage is based on theories of why the intervention will work given the particular situation and setting. Finally, theories will guide a social worker in the evaluation stage of the social work process by reassessing a client's biological, psychological, and sociological functioning and explaining the best time to end services.

Social workers assess for risk and needs and then recommend the best course of action for the client. The outcome is anticipated to be positive by alleviating or diminishing a presenting problem, however, it could equally lead to negative outcomes due to negligent practice. Therefore, social workers

should be held accountable for their work. One way to ensure accountability is to work within established theoretical frameworks, justifying the choice of theories and methods used based on evidence, and continually reflecting upon and evaluating the theories and methods used with the client.

The Relationship between Perspective, Theory, Method, and Model

Perspective, theory, method, and model are all important in understanding the role and significance of social work theory. A perspective is a particular value base or point of view that informs how one sees the world. A theory serves to explain or predict situations and provides a rationale as to the course of action that is needed to alleviate presenting problems. A method is the course of action taken to alleviate or diminish the presenting problem (method is often used interchangeably with intervention, practice, or approach). The choice of method is based on the particular theories that have been used to explain the current situation. A model is a structured and organized description of what generally happens in a particular type of situation.

Perspective, theory, method, and model are all equally important in social work practice as one concept depends, influences, or relates to another (Payne, 2014). Theories are generally developed based on a particular perspective. A perspective will influence the type of theories that are used in practice. Theories influence the methods that are selected, and models help to put theories into practice using specific methods. Therefore, social work theories can only be fully understood when considered alongside perspectives, methods, and models.

Types of Social Work Theory

Table 1 presents seven general types of theories that underpin social work practice, which are predominately developed within the professions of psychology and psychiatry and the academic disciplines of psychology, sociology, and philosophy. The following theories were selected as they serve as the basis for understanding human behavior, social interactions, and social constructions, which is required to conduct efficient and effective social work practice. The theories range from explanations of individual biological, psychological, and social development, to theories that explain psychological functioning, relationships, and social interactions, to theories that explain the societal influences on social order, construction of rules and norms, and explanations for inequalities and disadvantage. Table 1 includes the underlying perspectives and a selection of practice methods often employed when utilizing a particular theory.

Developmental Theories

Developmental theories explain the biological, psychological, social, and emotional development as stages over a portion (childhood, adolescence, adulthood, old age) or the whole of the life span. Many developmental theories focus on the development during childhood, such as Piaget's theory of cognitive development, which describes how a child (from birth to over 11 years) moves through discrete stages of cognitive development and intellectual growth to where she/he learns how to think and reason (Crain, 2011). Bowlby's (1988) attachment theory provides an explanation of how a child develops socially and emotionally based on her/his attachment to a primary caregiver, and subsequently the types of relationships and attachments that the child will possess as an adult.

Other developmental theories focus on individuals across the whole of the life span. Erikson's theory of psychosocial development consists of eight continuous stages of life that spans from birth to death and details how a person develops based on biological, psychological, and environmental factors (Crain, 2011). Each stage consists of a type of tension or crisis that an individual needs to work through to move to the next stage. Completing each stage successfully will result in more positive and healthy psychosocial development. Maslow's (1954) hierarchy of needs is a life span developmental theory that explains how individuals must have certain needs met before they can move to achieve a higher level of need. Maslow's theorized needs start with the basic physiological needs for survival and expands until the individual reaches the final need of self-actualization (a term often associated with humanistic theories). Additional theories focusing on the whole of the life span have examined faith, or spiritual, development (Fowler, 1981) and moral and ethical understanding and reasoning (Kohlberg, 1973). Although such theories influence social work practice, particularly through assessment, they have been criticized as being ethnocentric as they were developed based on Western (individualistic) societies, primarily with White men or middle-class individuals/families (Cianci and Gambrel, 2003).

Developmental theories influence social work practice by providing a basis for assessing and understanding a client's physiological, psychological, and emotional development. Such theories are primarily used in the assessment stage of social work practice where a social worker assesses the current level of development and functioning and uses this information to assist in explaining the client's situation, to determine the most appropriate form of intervention, and to hypothesize about future outcomes. Developmental theories are also useful during the evaluation and ending stages to determine any shifts or changes in levels of development.

Psychodynamic Theories

Psychodynamic theories focus on the psychological drives and forces within individuals that explain human behavior and personality. The theories originate from Sigmund Freud's psychoanalysis, which focused on the unconscious mind as the source of psychological distress and dysfunction. Psychoanalytic theory proposed the need for psychoanalytic therapy where the aim is to bring the unresolved issues, developed during childhood, or repressed trauma buried within the unconscious to the conscious mind in order for the client to begin to address these unresolved and underlying problems (Sharf, 2012).

Psychodynamic theories primarily deal with the unconscious motives that underpin an individual's personality and

Table 1 Theories used in social work practice

Theory	*Perspective*	*Practice method*
Developmental theories Includes: Cognitive development Attachment theories Life stage theories Theories of need Faith and moral reasoning	Developmental perspective	Assessment
Psychodynamic theories Includes: Psychoanalytic theory Ego psychology Object relations theory Self-psychology Crisis theory	Psychodynamic perspective	Psychodynamic therapy Psychoanalytic therapy Psychotherapy Jungian analysis Transactional analysis Crisis intervention Task-centered social work
Behavioral and social learning theories Includes: Behavioral theory Social learning theory Cognitive theory Social cognitive theory Group work theory	Social learning perspective	Behavioral therapy Cognitive therapy Cognitive behavioral therapy Cognitive-based transactional analysis Task-centered social work Group work

behavior. Childhood experiences are seen as critical in the development of the personality, behavior, and psychological thinking of an individual in later life, particularly psychological distress and dysfunction. Freud's drive theory, involving the three states of being (id, ego, and superego), are seen as important in understanding the role of the unconscious. The id is the unconscious that seeks self-gratification and fuels instincts, the superego is the conscious moral reasoning based on one's moral values and society's values, and the ego is the mediator between the id and the superego and seeks to make decisions based on the id's instincts and need for self-gratification and the superego's call for decisions based on moral values (Sharf, 2012).

Defense mechanisms, transference, and countertransference are terms often used when considering psychodynamic theories. Defense mechanisms are the tools used by the

unconscious mind to prevent anxiety caused by unresolved issues and trauma. The mechanisms distort reality and are used to protect oneself by distancing from reality. Common defense mechanisms include denial, disassociation, regression, acting out, projection, or displacement (Sharf, 2012). Transference explains the act of a client unconsciously projecting thoughts, feeling and experiences of relationships, or interactions with previous significant figures onto a social worker. Countertransference is where the social worker's unconscious responds to signals received from the client and the social worker acts out a particular role (e.g., taking a parenting role) (Ruch et al., 2010).

Additional theorists have expanded on the ideas of the role of the unconscious and have shifted the attention in psychodynamic thought from one that focused on conflict, to one that focuses more on relationships. Jungian analysis and therapy explores the conscious and unconscious, but is equally interested in extroverted and introverted personality, archetypes, symbols, and dreams (Sharf, 2012). Adler's individual psychology, more commonly referred to as differential psychology, explores the ideas of inferiority, superiority, birth order, and individual differences (Sharf, 2012). Klein's object relations theory explores how relationships developed in infancy and childhood are embedded in the unconscious mind and form the focus of individuals' drives, views of themselves and others, influences their personality in adulthood, and dictates how they interact in interpersonal relationships (Sharf, 2012). Kohut's self-psychology expanded on object relations theory, aims to focus more on the self and the deficits within the self (Sharf, 2012).

Crisis theory is also classified as a psychodynamic theory as it explains how people cope with stressful situations and how they have the capability to grow, develop, and change based on the crisis. The theory holds that individuals reach a state of crisis when their existing coping skills are unable to deal with stressful or traumatic situations resulting in psychological and physiological distress (Caplan, 1964).

Psychodynamic theories are useful in social work assessments to explore a client's past experiences, hypothesize about how such experiences are contributing to the presenting problem and how to address the problem (or crisis). In this sense, psychodynamic theories influence social work assessments as well as the interventions employed, such as psychotherapy, crisis intervention, or transactional analysis. Acknowledgments and understandings of defense mechanisms can assist a social worker in explaining a client's behavior, interpersonal relationships, or reactions to information. Considering the role of transference and countertransference can assist the social worker in building the social work–client relationship (Ruch et al., 2010).

Behavioral, Cognitive, and Social Learning Theories

Behavioral, cognitive, and social learning theories explain how individuals come to learn how to think, feel, and behave. Behavioral and social learning theories were developed by theorists who disagreed with the psychodynamic theorists. Instead, they hypothesized that individuals learn how to behave by cognitively and behaviorally responding to cues received from the interactions with their social environment.

The development of behavioral and social learning theories originated through experiments conducted by psychologists during the early 1900s that explored how animals can be conditioned to respond in a particular way. The studies from Ivan Pavlov and John Watson lead to the ideas of classical and respondent conditioning, which proposed that behaviors are the result of prior learning and can be learned and unlearned. The studies from Edward Lee Thorndike and B. F. Skinner lead to the ideas of operant or instrumental conditioning, which proposed that providing positive or negative consequences to behaviors lead to learning. Thorndike and Skinner found that positive consequences for behavior, or positive reinforcers, will lead to an increase in the occurrence of the behavior and negative consequences, or negative reinforcers, will result in a decrease in the occurrence of the behavior (Teater, 2014). Therefore, the behavioral theories postulate that behaviors can be learned, unlearned, and modified based on the reinforcers received from the social environment.

Bandura's social learning theory (1977) extends on the behavioral theory by stating that not only do individuals learn to think, feel, and behave through the receipt of reinforcers, but they also learn through observing and then modeling the actions of others. Individuals must observe a model (e.g., parents, teachers, media characters), pay attention to the behaviors or actions of the model, imitate the behaviors or actions, and receive a reinforcement (positive or negative) for modeling the behavior or action, which will influence whether the behavior or action is imitated in the future.

Cognitive theory is also a learning theory, but rather than addressing the learning of behaviors that occur merely through reinforcers from the social environment, cognitive theory aims to explain how humans are thinking creatures, who will make choices about their behavior based on what makes the most sense to them. Cognitive theory, as expressed through Ellis' ABC model, states that individuals experience an activating event (A), they process this event through their cognition and belief system (B), which mediates the behavioral consequence (C) (Sharf, 2012).

Behavioral, cognitive, and social learning theories are useful to social work practice as they provide a basis for exploring how behaviors are learned and unlearned; how a client's social environment can be positively or negatively reinforcing particular thoughts, feelings, and behaviors; or how a client's cognition and belief system can be contributing to problematic behaviors. Such theories are primarily used in the intervention stage of social work practice where a social worker attempts to modify or eliminate a particular thought, feeling, or behavior. Such interventions often used in social work practice are task-centered social work, cognitive therapy, behavioral therapy, cognitive behavioral therapy, or group work.

Humanistic Theories

Humanistic theories used within social work practice originated from humanistic psychology, which developed in response to the psychodynamic and behavioral theories that focused on human behavior and personality being determined by the unconscious or through reinforcers from the social environment. Humanistic psychology saw that these two prominent theories viewed individuals in response to events that they were not able to fully control and failed to view the individual as meaning-making and purposeful. Humanistic

theories stress the ultimate good of humans and their potential, creativity, health, hope, meaning, connection, purpose, and ability to reach self-actualization, or for individuals to achieve their full potential (Crain, 2011).

Phenomenology and existentialism are two theoretical schools of thought that underpin humanistic theory. Phenomenology is the exploration of conscious perspectives and experiences of phenomena and the meanings one attributes to such phenomena. Existentialism focuses on individual existence and the meaning one gives to her/his life. The central aspect to both phenomenology and existentialism is the lived subjective and conscious experiences of individuals, how individuals experience and attribute meaning to the phenomena to which they encounter, how they make sense of life, and how they make sense of their place and meaning within the world (Sharf, 2012).

The five core values of humanistic theory include the following: (1) human beings supersede the sum of their parts; (2) human beings have their existence in a uniquely human context, as well as in a cosmic ecology; (3) human beings are conscious – they are aware and aware of being aware both of oneself and in the context of other people; (4) human beings have some choice and, thus, responsibility; and (5) human beings are intentional, aim at goals, are aware that they cause future events, and seek meaning, value, and creativity (Greening, 2006: p. 239).

Humanistic theory can be found to underpin aspects of developmental theories, such as Maslow's hierarchy of needs, where an individual aims to achieve self-actualization, and Erikson's later stage of old age, ego integrity versus despair, as well as many therapeutic approaches that aim to explore and respect the experiences of individuals as humans and the meanings they attribute to such phenomena. Humanistic theory underpins Rogers' person-centered approach, which highlights the importance of empathy, unconditional positive regard, and genuineness in developing a therapeutic relationship that will lead to personality and behavioral change within the client (Sharf, 2012).

Humanistic theories are useful to social work practice as they provide a theoretical basis for viewing individuals, their experiences in the world, and the meanings they attribute to such experiences. Such theories are primarily used in assessment and intervention stages of social work practice. Using humanistic theories in the assessment stage would involve a social worker being empathic, having unconditional positive regard, and being genuine when interacting with a client in order to establish a relationship and fully see the client as an individual when assessing her/his situation. The intervention stage might involve a social worker employing interventions that would explore the client's experiences, meanings, hopes, and aspirations. Such interventions often used in social work practice are person-centered approach, existential therapy, counseling, gestalt therapy, hypnosis, meditation, motivational interviewing, and advocacy.

Social Constructivist Theories

Social constructivist theories focus on the creation of reality and how individuals view the world. The theories are related to the humanistic theories, discussed above, in that they were influenced by phenomenology as well as philosophical ideas of what is real and what is socially constructed. The basis of the modern social constructivist theories stems from Berger and Luckman (1966), who explored reality creation and the influence of individual meaning based on life experiences, societal and cultural expectations, rules and norms, which they termed 'social constructionism.' Since then, several theorists have refined social constructionism into three more specific theories, which emphasize either individual or social forces in reality construction (Teater, 2014). Social constructionism holds that reality is constructed through the use of language in interactions with others and is primarily influenced by history, society, and culture. Constructivism holds that reality is constructed more through one's biological forces through developmental processes, cognitive structures, and the human mind. Social constructivism combines both social constructionism and constructivism by placing the emphasis of reality construction on both societal and biological factors. There is a joint focus on reality construction being influenced by both nature and nurture.

Social constructivist theories have underpinned several theories often used within social work practice. Symbolic interactionism focuses on three core principles of meaning, language, and thought. The theory proposed that people use symbols (words, rules, roles) to give meaning and to make sense of the world. The meanings are transmitted to others through language. People are believed to interact with others and society, and assign meaning and symbols to these types of interactions and relationships (DeLamater and Myers, 2011). Future interactions are, therefore, dependent on the types of meanings and symbols one has attributed to that relationship or situation, thus, individuals act on what they believe versus what is objectively true. Communication theory holds that "people cannot NOT communicate" and that "all behavior is communication and all communication affects behavior" (Watzlawick et al., 1967). Role theory examines how people play out socially defined roles (e.g., mother, sister, wife, manager, teacher) and their ability to adhere to society's expectations of acceptable and unacceptable forms of behavior for the particular role (DeLamater and Myers, 2011).

Social constructivist theories are useful to social work practice as they provide a theoretical basis for understanding how realities and views of the world are individual-specific and created through a combination of interactions with society, the societal structures of history, culture, rules, and norms, and the meanings that individuals attribute to such interactions. Such theories are primarily used in the assessment and intervention stages of social work practice. Using social constructivist theories in assessment involves a social worker taking a position of curiosity with the client, using language to attempt to understand the client's reality and view of the world, and acknowledging that no two clients have the same reality of view of the world despite living through similar experiences. The intervention stage involves a social worker employing interventions that would explore the client's experiences and meanings and attempt to reframe thoughts or views that are contributing to the presenting problem into ones that are more acceptable. Interventions also include the social worker challenging societal assumptions or social constructs that are preventing the client from growing and developing. Such interventions often

used in social work practice are narrative therapy; social constructivist approach; solution-focused brief therapy; anti-oppressive, antiracist and antidiscriminatory practices; cultural competency; and advocacy.

Systems Theories

Systems theories are based on the belief that individuals do not operate in isolation, but rather grow and develop in interaction with their physical and social environment. Systems theories derive from general systems theory, which explores the parts of a system that interconnect and interact to make a complete whole (Teater, 2014). Within social work, systems can constitute individuals, couples, families, communities, organizations, society, and the world. Systems theories hold that each system should be viewed as consisting of several elements that make the system a functional whole, and each system should be viewed in relation to the other systems that can cause a change or reaction within the main system. For example, when working with clients, social workers should consider the bio-psycho-social aspects of the client by looking at physical and psychological functioning, social relationships, and community or societal structures that impact on the client.

The life model (Gitterman and Germain, 2008) of social work practice was greatly influenced by system theories as well as the person-in-environment perspective (Karls and Wandrei, 1994), both of which examine how social work is a unique discipline, in that it focuses on the point where individuals interact with their environment. Such systems theories aim to move social work practice away from focusing solely on the individual, such as with development theories, psychodynamic theories, and behavioral theories, and instead focus holistically on the individual within her/his environment (often referred to as human behavior in the social environment). Consideration of the environment includes the physical space, the social context, and the individual's culture and history. The aim of systems theories is to create homeostasis, or a favorable person–environment fit, in that the individual interacts and responds to her/his environment where interactions and change are contributing to positive growth and development and social functioning.

Family systems theory adapted the main concepts of general systems theory in understanding and working with families. The family is viewed as a system with each family member playing a critical part. Family systems theory holds that a change in one part of the family system will create a change in other parts of the family system, yet this is often variable depending on the boundaries of the family, the patterns, messages and rules of the family, and the family's responsiveness to change (Sharf, 2012).

Systems theories are useful to social work practice as they provide a theoretical basis for assessing a client holistically by examining all the systems within her/his environment. Such theories are primarily used in assessment and intervention stages of social work practice where the social worker assesses the client holistically by considering psychological, biological, and social functioning, as well as assessing the interaction of other systems within the client's environment, particularly those that could be contributing to the presenting problem. Based on the assessment, underpinned by systems theory, the social worker determines which system needs the intervention. Although the client may be an individual, the social worker may deem the family system, community system, or even political systems as the focus for intervention. Interventions most commonly used in social work practice include couple and family therapy, family systems therapy, community development, and community practice.

Critical Theories

Critical theories in social work aim to examine and critique social and political structures and functioning and their effects on individuals, families, and communities (Payne, 2014). Such critiques and understanding of social and political structures will assist in social work's aims of tackling inequalities and disadvantage, and promoting social justice. Conflict theory is a form of critical theory, based on the works of Karl Marx and Max Weber, which focus on inequalities within society, such as wealth, power, class, and how such inequalities impact on individual life experiences and chances creating conflict between and within social groups (see Hier, 2005 for a review of critical theories). Numerous critical theories have been applied to social work practice in an attempt to acknowledge the inequalities and disadvantage that clients can and do experience within the current social and political structures and to encourage courses of action and interventions that will challenge such inequalities.

Empowerment theory acknowledges that oppression is present within society and affects individuals and communities, yet individuals and communities do have strengths and resources and can combat such societal oppression (Adams, 2008). Individuals need to have power and control over their lives in order to obtain and use the resources necessary for positive growth and development, which can be achieved through individual and collective strategies. Feminist theory explains the inequalities between women and men, the oppression of women, the development and consequences of socially defined gender roles and seeks to explain how development and life experiences differ for women and men (Enns, 2004; Hyde and Else-Quest, 2013). Antioppressive, anti-discriminatory, and antiracist theories acknowledge the structural oppression and discrimination that impacts on clients and seeks to promote social work practice that challenges such structures by working individually with clients and participating and joining in social movements that, in turn, challenge oppression and discrimination within larger structures (see Dalrymple and Burke, 2006; Dominelli, 2008; Robbins, 2011; Thompson, 2006). Environmental and green social work applies a social work perspective to the ways in which environmental issues and crises can lead to disadvantage and limit resources, and focuses on targeting the social–political forces that impact on individual, community, and global well-being in order to promote environmental and social justice (Dominelli, 2012; Gray et al., 2013).

Critical theories are useful to social work practice as they provide a theoretical basis for assessing a client within her/his environment by acknowledging how societal and political structures and processes can be oppressive or discriminatory. Such theories take the focus away from blaming the client and examining other factors much larger than the client that could

be contributing to the presenting problem. Such theories are primarily used in assessment and intervention stages of social work. Assessment strategies involve the social worker examining societal and political structures and how these are impacting on the client (e.g., individual, family, community). Intervention strategies involve the social worker providing direct work with the client or participating in social movements and advocacy to eliminate structural oppression and discrimination. Such interventions commonly used in social work practice include advocacy; the empowerment approach; antioppressive, antiracist, and antidiscriminatory practice; consciousness-raising; crisis intervention; community practice; and community development.

Conclusion: The Application of Social Work Theory

The seven broad categories of theories range from a focus on individual psychological development to the influence of societal and political structures on human and communal growth and development. The profession of social work seeks to promote human growth and development as well as social justice; therefore, knowledge of the complete range of theories is necessary for effective social work practice although the choice and application will vary.

The use of theoretical approaches within social work practice will vary depending on social, political, and cultural structures, agency and organizational structures, and individual social worker preference. Social workers practice under legal mandates, which prescribe when and how a social worker can intervene. Such legal mandates are influenced by social and cultural values and norms, which dictate what a socially acceptable behavior is. For example, a social worker will utilize different theories when working with mental illness based on the social and legal structures that define mental illness, theorize its cause, and hypothesize about ways in which it is to be treated or not. Agency and organizational structures also dictate the types of theories, social workers use in practice. Agencies may specialize on a specific aspect of social work practice, such as mental health or community development, and will, therefore, utilize theories that help to achieve the agency's aim. For example, one mental health agency may work from humanistic theories and focus on person-centered counseling or solution-focused brief therapy to alleviate a presenting problem, whereas another agency may work from psychodynamic theories and concentrate on psychoanalysis or psychotherapy that aims to bring the unconscious to the conscious. Finally, the application of social work theories is dependent on the social worker's values and preferences. For example, one social worker may believe that behavioral change is initiated through conditioning (behavioral theory) whereas another may believe behavioral change is initiated through individual motivation (humanistic theory). The theoretical stance of the social worker will influence the choice of intervention (cognitive behavioral therapy vs motivational interviewing). It is important to note that the influences of societal/political, agency/organization, and social worker preferences may not be congruent.

Social work practice does not necessarily adhere to one category of theories, but often social workers must choose from a range of theories to create an intervention package that is suitable for the client. For example, a child welfare social worker may use developmental theories to explain the current developmental stage of a child; systems theories to conduct a holistic assessment of the biological family; social constructivist theories to understand the child and family's perspective; behavioral, cognitive, and social learning theories to hypothesize about how thoughts, feelings, and behaviors are contributing to the presenting problem; and critical theories to understand the context in which the child and family operate and in which the social worker practices. In selecting theories for practice, social workers must acknowledge that not all theories will be applicable to all clients and that theories that appear to fit in one situation will not always fit in similar situations. Social workers must combine theoretical knowledge with research evidence and reflections on practice to promote most accurately human growth and development and social justice.
